Vol. XVII.

JANUARY 1, 1889.

No. 1.

TERMS: \$1.00 PER ANNUM, IN ADVANCE;
2 Copies for \$1.00; 3 for \$2.75; 5 for \$4.00;
10 or more, 75 cts. each. Single num-
ber, 3 cts. Additions to clubs may be
made at club rates. Above are all to
be sent to ONE POSTOFFICE.

Established in 1873.

PUBLISHED SEMI-MONTHLY BY

A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS
than 50 cts. each. Sent postpaid, in the
U. S. and Canadas. To all other coun-
tries of the Universal Postal Union, 18
cts. per year extra. To all countries
not of the U. F. U., 42 cts. per year extra.

SOMETHING ABOUT BEE-HIVES.

FRIEND DOOLITTLE TALKS TO US ABOUT THEIR
PROPER SIZE, AND GIVES HIS REASONS.

I AM requested to give an article in GLEANINGS, on bee-hives. In doing this I will simply give the readers a little of my work in the past, and how I was led along step by step till I adopted the size of brood-chambers which I now use. When I first commenced to keep bees, all of the hives then in use contained from 2000 to 2500 cubic inches of space for a brood-chamber. After using such a hive for a year or two I came to the conclusion that this brood-chamber was too large, so I went to studying on the matter to see if I had concluded right. By many carefully conducted experiments I found that queens, as a rule, would not occupy more than 800 square inches of comb with brood for any length of time; hence it was plain to be seen, that, if I used a hive of the usual size which gave 1450 square inches of comb surface, I should have 650 square inches of comb to be occupied with honey and pollen. In case I hived a new swarm in such a hive, I should have from 500 to 600 square inches of comb filled with the best of honey, which would be from 25 to 30 pounds. We were told that this extra room was needed in case of a poor season, so as to insure honey enough for safe wintering. So each year my bees were wintering on from 25 to 30 pounds of the very best of honey, which should go into boxes, and be turned into cash; and in case of a poor season, the bees could be looked after; and if they did not have honey enough for winter, they could be fed sugar syrup, or given frames of honey, if we had such on hand.

Another thing, I found that, in having this amount of honey stored in the hive, the bees were very loth to commence work in boxes afterward; for in doing this they got to crowding the queen, and also they had sealed honey next the sections, instead of brood, which brood all know is a great enticer into the sections. In order not to get any pollen in the sections, I allowed 200 square inches of comb (above the 800 the queen occupied) for that, so I had 1000 square inches of comb space, or about 1500 cubic inches as the right size for the brood-chamber, regardless of what style of frame is used. Of course, the frames will not always give just the number of square inches inside of them which is required, but we can use the number which comes the nearest to it. For instance: I use nine Gallup frames, which give 1035 square inches of comb; while if I used but eight it would give me but 920. To get the square inches of comb in the frame, multiply the length by the depth, then use the number of frames which comes the nearest to 1000 inches. Mr. Gallup used 12 frames in his hive; and as he was my teacher, I, of course, used the same number when I first began. When I came to see things as above, I reduced them to nine by using three blank boards, or dummies, in place of the frames. The number of frames can be reduced at any time in any hive, in this way, with but little expense, and that, too, without disturbing the hive at all, or altering the space given to surplus above. These boards I made of inch lumber, the size of the inside of the hive (fitting loosely) below the rabbets, with the top-bar of a frame nailed thereto, so that it hangs in the hive just like a frame. Later years I have used what is termed "the contraction method," and think that at times

there is an advantage in it; but, so far as I have now explained, there is no contraction about it, for this is as large as I would have a hive when working for comb honey, as it gives the queen all the room she will occupy, and more room than this is worse than useless. Hives should be made so that all of the bees can be kept profitably at work; and if you have a three-frame nucleus well supplied with bees and queen, you should be able to get just as much comb honey from it in proportion to its numbers, as from a full colony. Unless a hive is calculated for this, it is lacking just one important feature. Hives as above described require less manipulation to secure good returns from them than do either larger or smaller hives; yet, do and say what we will, it is the management of hives that gives the practical apiarist good returns of snow-white comb honey—such as sells readily in any market in the world, when a second quality will go begging. Whatever hives we may use, they must be diligently looked after from the time spring opens till the bees are ready for winter; and unless a person can thus do, he had better not go into apiculture expecting to make a success of it.

As hinted at above, one secret of success in getting comb honey is to get the brood-combs all occupied with brood before the honey harvest opens, so that, when it does commence, the bees are obliged to put the honey in the sections. If we use a small brood-chamber it will be seen that the brood comes clear to the tops of the frames or hive, and consequently very close to the sections; hence the bees readily enter them, while with a large brood-chamber, the bees store the comb the queen does not occupy, with honey at the beginning of the harvest, so that the sections are excluded from the brood by several inches of sealed honey, which, not liking to pass over, the bees often refuse to go in at all. Gallup saw this point, even though he advocated a large hive; for he said, more than 25 years ago, "We should never allow the bees to get in advance of the queen; for if we do, the prosperity of the colony is checked at once; that is, if the bees are allowed to fill the combs with honey in the spring before the queen has filled them with brood, the colony will be an unprofitable one." This point is one well worthy of our closest attention; and it is only as we look to all of these points, and bring them into line with our work, that we can expect to meet with the greatest success. I have given this article thus early, so that all who are thinking of making hives this present winter can try a few as above, so as to see if I am right.

Borodino, N. Y., Dec. 16, 1888. G. M. DOOLITTLE.

SWEET CLOVER.

ITS VALUE AS A HONEY-PLANT IN THE REGION OF
SALT LAKE CITY.

BEING requested by the editor to write an article on the above subject, I have written up the habits, etc., of the plant. Some of the points which I shall give are probably known to a great many of the fraternity, but I think they will bear repeating.

Sweet clover grows here along the water-courses, moist waste places, along the roadsides, and in neglected fields. It grows from six inches to as many feet in height, according to the location, and it is covered with an abundance of bloom from top to bottom, yielding in most seasons an abundance

of nectar, which, after being gathered and stored, produces honey of the very best quality and color. It does not generally bloom in the first year; but in the second it commences about the first of July, and keeps up a continual bloom until killed by frost, furnishing bees with pasturage, generally from the middle of July until the latter part of August.

Sweet clover is sometimes used for pasturage, and also for making hay, if cut when young, though it is a long way behind alfalfa for that purpose. Though it is sometimes relished by stock, very few would sow it for feeding. If eaten while green it is in a measure a cause of hoven, or bloat, in cows. If you wish good milk or butter you had better not feed it to milch cows, as it imparts a very disagreeable taste to it. If eaten off by stock it will soon recover, and produce an abundance of bloom for the bees.

It is a very fair fertilizer; and it is also claimed that, if planted on alkali land, it will feed on the alkali and exhaust it, besides bringing to the surface, with its long roots, elements necessary to plant-life.

As sweet clover is a biennial it is not a very hard weed to eradicate, and very seldom troubles cultivated fields, though it will sometimes seed a field; and if such field is planted to grain the following season, it will come up, and is cut off only with the reaper. Next season, if the same field be neglected, it will quite likely be covered with sweet clover, and that, too, sometimes as high as your head. If a field is cultivated as it should be for two seasons, the clover will entirely disappear. The plant requires a little moisture in the soil the first year; but after that it will grow without. I consider it, for my part, a great deal better to see a roadside lined with it than the sunflowers, etc., that generally grow in such places.

Now, to sum up, sweet clover is our main honey crop in this locality. It is our best honey; and said honey, I may say without boasting, compares favorably with the best grades known.

I do not think it will pay to sow it for honey alone, unless on such land as is considered worthless; but I think it would be a benefit to such land.

As to the amount of nectar it will produce per acre, I am unable to say; but I think it will compare favorably with white clover; in fact, I think that it produces fully two-thirds of our honey crop in this locality, and I should consider this a poor country for honey, if it were destroyed; but as it is, we generally get a crop; that is, the bees generally have some honey to spare.

J. C. SWANER.

Salt Lake City, Utah, Dec. 22, 1888.

I would say to our readers, that it seems to me friend S. has been quite careful and conscientious in giving the objectionable features of sweet clover in the region of Salt Lake City, as well as the good qualities. In that locality there are a very few plants that will stand the fierce drouth of summer; but sweet clover seems to be one of them, and it might be easily grown on thousands of acres that now bear nothing but weeds of no value. Much of this desert soil is so light that it is very easily prepared for a seed-bed. After sweet clover has once got a start, it furnishes about as permanent bee-pasturage as any thing I have ever found. In fact, I could not find any

of the bee-keepers around Salt Lake City or Ogden who say they ever have seasons of no honey at all, such as we have had here several times during the past twenty years. Not only does sweet clover yield honey, but, after testing it in a good many places, I pronounced it equal in appearance and flavor to any honey we have in the world. When my Notes of Travel get far enough along to reach it, you will see what I wrote down on the spot. The first time I tasted it at friend Woodmanse's I uttered an exclamation of surprise, and asked him what was the source of the beautiful honey. Even before he spoke, there seemed something familiar in the delicate flavor; and when he said sweet clover, I recognized it as plainly as if it were but a piece of stalk in my mouth. It tastes very much as sweet clover smells when its green leaves are bruised slightly. The flavor is not rank enough to be at all disagreeable. The extracted honey is very thick, and has the same beautiful flavor as the comb honey. It seems to me that these facts give us a wonderful opening for starting a honey-farm where land is cheap, and nothing else will grow on account of the long severe drouths. We should be glad of more facts from those who have had experience with it in desert localities.

THAT WINTERING PROBLEM.

IS IT OR IS IT NOT SOLVED?

ON the 9th of December, and Sunday at that, I had to set all my strong colonies out of the cellar. It is just one month since they were set in, during all of which time as a whole it was too hot to control them. The result is, most of them have symptoms of disease. They had a good flight, which may help them some. I worry more over the wintering problem than all other features of bee-keeping put together. No wonder that I devour every scrap of bee-lore on this topic that falls within reach. Some time ago, Mr. Heddon came out in his prospectus, "The Wintering Problem Solved." This was taking. 'Twas enough to sell a thousand copies at one clip. If I remember, he stated that "bees could be wintered with the certainty of our domestic cattle." Surely, then, in the interest of our pursuit it is only fair to ask Mr. Heddon if he has been able to do so.

I wish he could say yes.

I was gratified to observe in the November issue of the *Review* the semblance of unity in one feature of cellar wintering. I felt thankful for that number; for, as it turns up in practice, we have a great deal that conflicts with the theorists. I hold, that, so long as a batch of men continue to disagree, and that, too, upon points where "location" won't close up the breach, to put it honestly, I refuse to believe that they know whereof they affirm. Have we been able to safely anchor any of the speculative barques upon the sea of apiculture? I have thought, so far as GLEANINGS is concerned, that Uncle Amos ought to have been a sort of supreme court from whom there was no appeal. But instead he says, "Boys, let us shake hands across this bloody chasm. Can I sell you any thing to-day?" I am deeply interested in all that

pertains to the honey-bee. I love light and truth, and would follow it; but as it turns out, I am chagrined to think that, after all, I have been following the blind gropings of a Cyclops around the walls of his cave.

I. HAMILTON.

Beason, III.

Friend H., Mr. Heddon can answer for himself. Does the expression, "Can I sell you any thing to-day?" exactly fit Uncle Amos? If you will prepare your bees in chaff hives, as directed in the A B C book, I feel sure they will winter just as well as our bees do, *year after year*, here at the Home of the Honey-Bees. My experience is, that those who work on Sunday usually have trouble.

CABBAGE AND CAULIFLOWER FOR '89.

H. A. MARCH ASKS ABOUT THE JERSEY WAKEFIELDS.

FRIEND ROOT:—I asked you to give me some reports (good or bad) on the cauliflower seed I sent you for trial. I haven't received a bad report yet. If yours is bad it may take a little of the conceit out of me, for I begin to think I can raise better seed than they raise in Germany or Holland; and, what is better, I can raise it at *less than half* the price it costs there. I sent, as you advised me to, some samples to W. J. Green, Columbus, and this is what he says:

All of the varieties sent give satisfaction. One thing is noteworthy about your seed; and that is, its large size and great vitality, producing very strong healthy plants. If you can grow seed equal to that sent us, you need not hesitate to make high claims for it.

You see, this is a new industry. Cauliflower seed, I believe, has never been grown in this country by field culture before I made the trial here on Puget Sound. All of the best seed has been imported from Erfurt, Germany, at a cost of about \$40.00 per lb. Now, here in Washington Territory we can raise just as good seed for \$15.00 per lb. But prejudice is so strong in favor of imported seed that dealers are afraid to come out and offer the seed on its own merits. The question is, How shall I push my seed forward so that people can get cheaper seed? Can you advise me? What do you think of this plan? Get the address of all the experiment stations in the country, and send them samples for trial, and publish their reports in a paper like the *Rural New Yorker*. How to get their address, that is the next thing. Can you tell me how that can be done?

H. A. MARCH.

Fidalgo, Skagit Co., Wash. Ter.

Well, friend M., we raised so many cauliflowers we could hardly sell them or give them away; for, to tell the truth, for a long while we offered cauliflower at the same price per pound as we sold Jersey Wakefield cabbages. But our Medina people are so little accustomed to using cauliflower unless it be for pickling, the cabbage rather took the preference, even though the price was alike—3 cts. a pound. During the fall we had rather better demand when they commenced using it for pickles, and we have quite pretty heads of Snowball cauliflower down in our greenhouse at this date, Dec. 27. Will the friends who tested the cabbage and cauliflower seed last season please tell us briefly how the seeds turned out? If I understand it correctly, friend March does

not care to sell seeds at retail, so you may send your orders to us, if you please. Should you wish seed, however, to sell again, perhaps the better way would be to buy directly of friend M. The above letter was probably not intended for publication; and while friend M. thinks he can, on a large scale, raise cauliflower seed at \$15.00 a pound, I presume none of our readers will understand that he proposes to sell a single pound at that price. In regard to the address of the experimental colleges, I think our readers in the different States can give friend M. the addresses he desires.

SELLING EXTRACTED HONEY.

MRS. HARRISON GIVES US SOME OF HER EXPERIENCE.

A BEE-KEEPER of this State wrote to me to know if I could not sell extracted Spanish-needle honey, put up in twenty-gallon kegs. I made inquiries, and the result was something like this: Going into a drugstore, the proprietor said, "Buy a twenty-gallon keg of honey! Oh, my! that would last us twenty years. I would buy twenty pounds." After trying the retail drugstores I went into a large wholesale establishment. In answer to my inquiries the proprietor said, "I had some difficulty in obtaining honey this fall, but I have a supply now. I had honey in barrels offered me at 7 cents per pound; but I did not want it. What I bought is put up in tin cans, like fruit, and will not granulate. I paid from 12 to 14 cents per pound for it."

I kept thinking about that honey that would not granulate, so yesterday I took the street-cars and went to buy a can. There was a placard stuck up, saying, "No goods sold at retail." The clerks said no. I went to the proprietor, and told him I wanted to buy a can of honey; that I had honey at home, but that I wanted to learn how the trade preferred it put up. He put a speaking-tube to his mouth, and soon had a can upon his desk. I paid 45 cents for a three-pound can.

I weighed this can just now, and it weighed 3½ pounds—honest weight, surely. The cover was fastened down with something like plaster of Paris, in lieu of sealing-wax. I dug a little place at one side with the point of a knife, and easily pried it up, with the sealing attached to the cover. I should think the can would hold 4 pounds, as there is more than an inch of space above the honey.

WHAT I FOUND IN THE CAN.

The children had a great deal of curiosity to see what was in the can, as well as myself. The first thing I saw was three legs, and a wing and a leg together, floating, which had once belonged to the busy workers. Perhaps these were put in as an evidence that it was *bee* honey, as the label declared it to be—just as an Irish girl, seeking a situation, showed her hands on being asked if she could make bread. "Sure, here is the dough under me finger-nails from my last baking." I took a saucer and teaspoon, and dipped out some of the honey, and then went out to the honey-house with another saucer and spoon, and brought in what I knew to be basswood honey, while the baby stood by saying, "What are you going to do, mamma? Compare it. I can tell it. That one is brown, and this one is yellow." She was correct. Our basswood is a light

yellow, while that from the can was dark. The can is labeled, "White clover and basswood," and below it says, "It is not possible in all cases to have the contents of each jar entirely from the blossoms named, yet sufficiently so to give distinctly their characteristic flavor."

I saw that this honey was the product of this county, and was puzzled to know how it could be white clover, as it has failed here for two years. The label should have been erased, and "fall flowers" put in its place, as it is thick, well-ripened honey, the product of Spanish needle and other fall flowers. It will injure the trade in honey in cans, if it is not what it purports to be. The honey is liquid on top, but about as thick as hasty pudding below. I will make a selection from a letter before me, with reference to Spanish-needle honey granulating.

"I have been in the bee-business for 15 or 20 years; I keep my honey in barrels and cans for a year, and never had any granulate enough so but that it would run out of a bung-hole whenever the weather was not too cold. Nine-tenths of our honey is Spanish needle, which does not granulate when well ripened; but if extracted too green (if that is the word) it will granulate."

In purchasing this honey I thought I was going to find out how to put up honey so that it would not granulate, which would be a bonanza to bee-keepers, but I failed. The proprietor of the drugstore thought so, but was mistaken. Our basswood honey is liquid up to date, Dec. 7, but the weather has been uncommonly mild. It is in a tin can which has a cover that fits down closely, while a jar standing near containing mixed honey with a cloth tied over it is solid. I infer that honey that is exposed to the air granulates sooner than that which is not; for a pitcher of basswood honey that I kept to pour out of to customers is now solid.

Peoria, Ill.

MRS. L. HARRISON.

Mrs. H., there is something a little singular about that inscription on that can of honey you bought. The first extracted honey we ever put up, nearly twenty years ago, I began labeling "White Clover," "Basswood," etc.; but an old bee-keeper at once commenced finding a good deal of fault. He said that the bees never gather honey entirely from one source, and that I could not possibly furnish a jar of honey that was all of white clover, or all basswood, etc. I admitted the truthfulness of his criticism, and at once added to the label the words you quote—"It is not possible in all cases," etc. As you have given it word for word it is a copy of my label, for it could not have been otherwise. I believe that any honey is much less liable to granulate when left in the hive until it is thoroughly ripened by the bees. I do not know what process they put it through, but they seem to know better than anybody else just what to do to honey to prevent granulation. I believe that it is at least generally true that well-ripened honey from Spanish needle seldom if ever granulates. We have had it a great many times, and kept it where it was so cold you could almost cut it with a knife, but there was no granulation. Of course, every bee-keeper or packer of honey should be very careful to have the label state correctly the contents of each can or jar.

CARRYING HIVES INTO A WINTER REPOSITORY.

DOOLITTLE'S METHOD CRITICISED.

FRIEND ROOT:—I have read with considerable surprise friend Doolittle's article in *GLEANINGS*, Nov. 1, on placing bees in the cellar. My surprise is, that one person should attempt to handle hives at all without assistance. Friend Doolittle must be a modern Samson. The most of us frail mortals certainly prefer help on such occasions. Where I formerly lived, the apiary was 75 or 100 yards from the cellar, and down hill. We used to employ the two strongest men the town afforded, to carry the bees into the cellar, beginning after supper, and finishing about 10 o'clock. We have paid as much as \$3.00 for the job. We used a stretcher, carrying two hives at a time, but it was so laborious that I finally insisted on one hive at a time. It is surprising how much lighter one hive is than two. I suppose figures will not lie, but it certainly seems much more than as light again. My apiary is now near the cellar, and level walking, except the decline of two feet into the cellar, which extends a space of sixteen feet. I have 68 hives. With the aid of a student I took one-half into the cellar the evening of Nov. 21st, and the next evening took in the rest. This comes under the head of light work when managed in this way. The cost was 50 cts.

I wish to say right here, that I can now manage my bees alone, with one-third the expense, bother, and work, that it took the entire family of seven, eight or ten years ago. So much for experience.

Now to return to the subject. By carrying with a stretcher there is no occasion whatever for any jarring, unless it be when the upper hives are tiered in the cellar. How, under the sun, Doolittle can pile up his fourth hive, and no bottom at that, is more than I know. I should very much discourage both methods of carrying in bees, of which he speaks. I like the plan of generous ventilation from below, except that I fear my bees would all come out on me, especially when taken down to carry out in the spring. They are always very uneasy at that time.

I have tried an experiment in the way of wintering this time. I have often thought that the bees were too warm in the cellar, with the heavy airtight mats over them, so this time I took off every thing except the piece of burlap, folded it, and covered only the front half of the frames above. This leaves half the hive exposed to the air, and free access into the cover. It may prove a great mistake, but I do not see why. The cluster can doubtless retain sufficient heat to keep the brood if they have any. I suppose, friend Root, you are well aware that the bee does not believe in ventilation at all (ought to be a railroad conductor), as it will seal every crack in the hive except the one small entrance. I have often thought that, if Nature ever made a mistake, it was in this case with the bee. However, perhaps in the natural wild state of the bee this sealing is quite right.

JOHN F. WHITMORE.

Grinnell, Iowa, Nov. 29, 1888.

Friend Doolittle is a big man in two senses of the word. We have not a particle of doubt but that he can lift easily the hives, and carry them into the cellar in the manner

he describes. Perhaps friend Miller's method, described on page 962, Dec. 15, 1888, would be more to your liking.

ANOTHER METHOD OF PERFORATING ZINC.

SOME OF ITS ADVANTAGES AND DISADVANTAGES.

FRIEND ROOT:—Inclosed you will find a sample of zinc, such as I have been using in the queen-excluding wood-zinc honey-boards. I believe this plan of perforating is preferable to the two parallel rows of holes as usually made.

SHEPHERD'S PERFORATED ZINC.

It certainly gives more openings than any other plan, and at the same time leaves it sufficiently rigid for all purposes. I will also say, that the work was done on a home-made machine that does the work as per sample, as regards quality; and the cost was but small. M. W. SHEPHERD. Rochester, Ohio.

At first sight, friend Shepherd, we thought your plan of perforation had some very decided advantages; but the more we consider it, the more we are convinced that nothing is gained; but, on the contrary, there is an attendant loss. You have longer perforations, it is true. Those in our zinc are very nearly $\frac{2}{16}$ of an inch long. Yours are $\frac{1}{8}$, making them about an eighth of an inch longer. There may be some advantage in lengthening the openings; but when ordinary perforations are long enough to admit worker bees, why make them any longer? The short perforations might go a great way toward keeping a good long queen from going above, whereas the longer ones might admit her, if she were a slender one. You say your zinc certainly gives more openings to the same amount of space. By laying a strip of your zinc upon a strip of ours, we find that there are more perforations in the same space in ours. If your perforations were the same length, it would make about an equal number of holes.—Another disadvantage, as it seems to us, in your plan, is, that the openings take too much space between the break-joint slats. This would reduce the latter, on $1\frac{1}{2}$ spacing of the frames, down to $\frac{1}{4}$; then if you allow for necessary depth of saw-kerf there will be little solid wood ($\frac{3}{8}$) left.—The perforations can be made about as easily on one plan as on the other. Those having hand-made machines, or machines which make a single perforation at a time, can very easily perforate the zinc in the manner shown, by simply changing the feed.

We should be glad to know what Dr. Tucker would have to say upon this method of perforating.

OUR TIN-SHOP.

PERFORATING MACHINE, ETC.

LET'S see. We have given our readers a view of our factory, a glimpse into our saw-room, and one of our office. We now take pleasure in giving you a photographic view of our tinning apartment. The picture is an exact reproduction by the Ives process, and, of course, every thing appears just as it did when photographed, which was one afternoon immediately after shutting down. The view shows perhaps a little over one-half the room. Our tin-shop, including paint-shop, is one spacious apartment 44 x 96

regular intervals. A foot-treadle, shown in the foreground, can be so operated as to throw on or off the power at will. If a punch should happen to drop out, as it did on one occasion, or something else should get out of order, the machine can be instantly stopped, and thus avoid an expensive breakdown. A man stations himself in the rear, picks up a sheet of zinc, 28 x 96 inches, from the floor, and places it on the table. He then slides the two ratchet-bars back far enough to fasten the ends of the zinc to them. A pressure of his foot upon the treadle sets the machine to perforating. At every chunk of the great jaw, 70 little oblong pieces of metal drop down into a

OUR TIN-SHOP, WITH THE ZINC-PERFORATING MACHINE IN THE FOREGROUND.

feet, and in it are something over 40 tinning-machines.

"What do you call this machine just before us?" you ask.

"Why, that is our new zinc-perforating machine." Unfortunately, the engine has just shut down; but a sheet of zinc has been passed half way through. The balance-wheel is connected by a belt to a pulley below. The two sets of cog-wheels, in connection with the connecting-rods, as you will readily perceive, give immense power to the punches, 70 in number, inserted in the sliding carriage. Lying on the front platform, and on either side, are two ratchet-bars. A couple of dogs, operating upon these, cause the zinc (to which the bars are attached) to be fed through the machine at

keg. When several kegs are full they are sold with their contents to junk dealers, who gladly pay us enough for such scrap zinc to fully pay for the time of a man and the machine for perforating the sheets. We are thus enabled to put the price of perforated zinc down to nearly the cost of the raw unperforated metal.

The capacity of the machine is something over a thousand feet of metal per day; and so great has been the call for it that we have sold during the past year about 30 casks of zinc, and our past trade has been such that we feel warranted in believing that we shall sell very nearly double that amount in the near future.

We have given you these facts in order that you may get some idea of the demands

of bee-keepers for perforated metal. Where, a few years ago, we sold our tens of square feet, we now sell our thousands. The question is often asked, "Is the zinc practicable, and is it going to be of value to bee-keepers in working for comb or extracted honey?" If its large sales mean any thing, it would seem that there are some bee-keepers at least who regard it as of great practical utility.

But, what are these other implements which we see? Those are tinner's tools and machines, such as you will find in a first-class well-equipped tinning establishment. Indeed, in order to turn out and supply the demands of bee-keepers for the various articles made of tin, it is necessary to have such an equipment. We find in looking over our books that we sell from 800 to 900 extractors, from 12,000 to 18,000 smokers, from 1200 to 1500 square 60-lb. cans, and every thing else in proportion, such as tin receptacles for holding honey, besides a great variety of other implements of use in apiculture, which can not here be described. Without tinner's and tin-shops, bee-keepers would have to dispense with a great many useful appliances connected with the pursuit.

THE COMMON HOUSE-FLY.

PROF. COOK TELLS US OF THIS FAMILIAR ACQUAINTANCE OF OURS.

MR. CHARLES SITTS, Brosie Corners, New York, requests that I write up the history of the common house-fly, for GLEANINGS. I do not wonder that any one should feel an interest in an insect that forms such an important factor in our domestic affairs as does this insect. It eats our pudding with us, and even out of the same dish. It daintily sips not only of our tea, but of the cream and the sugar that season it. No wonder the great Swede, Linnæus, named it *Musca domestica*. It rooms with us, eats with us, drinks with us, and any one accustomed to take afternoon naps would be glad if it would only sleep with us.

This fly is too well known to need description. It belongs to the order *Diptera*, as it has two wings, suctorial mouth-parts—flies and mosquitoes stab and suck but do not bite—and passes through complete transformations. By this last we mean that the first stage—maggot—is not at all like the succeeding stages of the insect. It belongs to the family *Muscidæ*. Such insects have short antennæ, with a full plume on the last joint, and heavy short bodies. This fly hibernates in winter as a fly. Fortunately, most of them never wake to life in the spring; but enough of them survive to make things lively about August and September. The house-fly lays more than 100 whitish elongated eggs. These are laid in horse manure, on which the maggots feed. The eggs hatch in about twenty-four hours. The larva, or maggot, looks very much and is very much like that of the meat-fly, or blow-fly, with which all are doubtless familiar. When fully grown it is from one-fourth to four-tenths of an inch long, and is about one week in getting its full growth.

This fly, like many others, pupates in its last larval skin. It is rounded and seed-like, as a pupa.

Such pupæ are called puporiums. The pupa state lasts about a week. We now see why these flies become pretty numerous along in dog-days. Each female lays more than one hundred eggs; and the time from egg-laying to maturity is only about two weeks. Most of us have studied geometrical progression. Here we see it illustrated. Suppose one fly commenced "to multiply and replenish the earth" about June 1st. June 15th, if all lived, would give 150. Suppose 75 of these are misses. July 1st would give us, supposing no cruel wasp or other untoward circumstance to interfere, 11,250 flies. Suppose 5625 of these are females. We might have, July 15, 843,750 flies. For fear of bad dreams, I will not calculate what might be by September 15th. Some of us who have some time stopped at third-rate hotels quite understand it. From what I have said, it is easy to see how that a horse-stable near the house is favorable to the fly nuisance. Slops about the wood-shed, of course, attract flies. So the neat tidy housewife is less tormented than one not so blessed with this kinship to godliness.

We provide in three ways against these pestiferous house-flies. First, we have screens to all our windows, and to such doors as are much used, especially the outside doors to kitchen and dining-room. The screens to the kitchen windows are full length, so the windows can be opened either from above or below. We believe in fresh air; and with this arrangement we get it. Secondly, the screen to the pantry window, to each of the dining-room windows, and to one window of each of the other rooms, is hinged at the top to the upper sash. Thus by darkening all the other windows, the flies alight on this hinged screen. We now push the screen quickly out at the bottom, brush rapidly with a palm-leaf fan, and, lo! the flies are all outside the window.

Thirdly, in case the flies get too thick we use pyrethrum, or, better, California pyrethrum, or buhach. Toward night we try to attract all the flies into the kitchen by darkening the other rooms, and placing odorous sweets, exposed in that room. At ten o'clock—bed time—we scatter, by means of a ten-cent bellows, a little of the powder into the room. The next morning the flies are dead, or partially paralyzed, on the kitchen floor, and are swept up and cremated in the kitchen stove before any revive. Mrs. Cook prefers the hinged screens, in the main, as too free use of the pyrethrum does spread a fine dust on the furniture, which is not desirable. A. J. Cook.

Agricultural College, Mich.

Friend Cook, I am exceedingly obliged to Mr. Sitts and yourself. One needs, however, to go to California to find house-flies in perfection. There is not any winter there to kill them, and so they just keep on in that geometrical rate of progression of which you have been speaking—that is, unless the careful housewife makes too vehement a protest, or unless somebody decides that prevention is better than cure, and stops the progression. Now, I want permission to introduce a very disagreeable subject, and I do not know any way to tell it without having some of the friends feel like holding their noses, even if they decide not to do it. I am sure you are right in saying that flies are bred around stables, for at one time our printers used to set type close

to livery-stables, and the flies were not only numerous, but they were mean and low-lived. I think, however, the stables could be managed so as to breed fewer flies. When I was a small boy I sometimes used to neglect cleaning the stables, when father was gone, until the manure became full of maggots. These were probably, as you state it, the larvæ and pupæ of the house-fly. The chickens, however, used to follow me so that there were not so many flies raised after all, if I cleaned the stables in season. I had learned in my childhood, also, that flies came out of manure by some process, for I have seen them crawl out by the hundreds; but I made up my mind at the time that there were different kinds of flies that lived in the manure. Now, then, comes in the place for you to hold your noses. In many out-buildings, where the excavation is very shallow, and the contents of the vault are exposed to sunlight, these same larvæ and pupæ can be seen by the millions, I was going to say; and the flies go straight from these revolting and disagreeable places directly to the kitchen and dining-room; and I have wondered whether they did not carry typhoid fever along with them. Dry dust, peat, or properly arranged out-buildings, will, if I am correct, entirely stop the hatching of flies around these places; and I feel sure that you agree with me, that much might be done to abate the fly nuisance by prevention in the way I have suggested. Now, friend Cook, please tell me if I am not right about it. Our shorthand writer asks if lime, copperas, or some other chemical, will not carry death and destruction to them as well as sweeten the premises. It is a matter of such vital importance, that we can well afford to take a little space for it. Is not prevention better and cheaper than pyrethrum?

THOMAS G. NEWMAN.

BIOGRAPHICAL SKETCH BY DR. C. C. MILLER.

FOR fifteen years the *American Bee Journal* has remained under the management of one man; and, aside from being ably edited, its general make-up and clean typographical appearance impress one strongly, that, somewhere connected with it, is a man who is well up in the art preservative of all arts. The secret of it is, that Thomas Gabriel Newman, its proprietor, is himself a thorough practical printer. Born near Bridgewater, in Southwestern England, Sept. 26, 1833, he was left fatherless at ten years of age, with three older brothers and a sister, the mother being a penniless widow by reason of the father's endorsing for a large sum.

The boys were all put out to work to help support the family. Thomas G. chose the trade of printer and book-binder, serving an apprenticeship of seven years, and learning thoroughly every inch of the business from top to bottom, in both branches.

Early in 1854 he came to Rochester, N. Y., where he had relatives; and before noon of the day of his arrival he secured a permanent situation in the job-room of the *American*. Within two months he took the position of assistant foreman on the

Rochester Democrat, then the leading Republican paper of Western New York. Later on he spent seven years editing and publishing a religious paper, called the "Bible Expositor and Millennial Harbinger," in New York, and published a score or more of theological works, some written by himself. In 1864 he moved it to Illinois, sold out the business, and, for a "rest," took his family to England. Returning in 1869 he located at Cedar Rapids, Iowa, where he published and edited its first daily paper. In 1872 he sold this and removed to Chicago, where he embarked in the business of publishing *The Illustrated Journal*, a literary serial printed in the highest style of the art, and magnificently embellished. The panic of 1873 ruined this luxury, bringing upon him a loss of over \$20,000.

In 1873 a friend introduced him to the Rev. W. F. Clarke, who wanted to dispose of his interest in the *American Bee Journal*, which interest was one-half,

THOMAS G. NEWMAN.

subject to an unpaid contract. This he bought, and afterward the interests of F. Grabbe and Geo. Wagner, thus becoming sole proprietor. For a man not afflicted with the bee-fever, in cold blood to pay more than \$2000 for the simple "good will" of a paper with no printing-office or supplies of any kind, shows an unbounded confidence in the future of bee-journalism. Few men under the same circumstances would have achieved his success. For three years he employed successively as editors, Rev. W. F. Clarke, Mrs. E. S. Tupper, and Dr. C. C. Miller, meanwhile applying himself to the study and practice of bee culture, increasing his apiary from three colonies, purchased for experimental manipulation, to more than 100 colonies in 1879, when he disposed of them because troublesome to surrounding stores. For the past 12 years he has been sole editor, having called to his assistance the

most successful honey-producers of the continent. With a positive dislike for financial transactions, he is fortunate in his son, Alfred H., who has ability in that direction. Besides this son he has two daughters, all married, and five grandchildren.

In 1879 he went to Europe, at his own expense, as American representative to the various bee-keepers' societies, and attended conventions in England, France, Italy, Austria, Germany, etc., and was awarded several gold medals for exhibitions of American apiarian implements. He has been elected an honorary member of 14 bee-keepers' associations, and is also life member of the North American Bee-Keepers' Society (of which he was twice elected president), and treasurer of the Northwestern Bee-Keepers' Association.

He has been twice elected Grand Commander of Illinois of the "American Legion of Honor," and is an officer of some ten different societies in Chicago, social, fraternal, insurance, etc., and spends much time in visiting the sick and relieving the distress of those in fraternal and social relations with him, thus fulfilling the injunctions of the Book of all books, of which he is a diligent student.

In 1885 he was elected the first manager of the National Bee-Keepers' Union, which, under his management, has successfully defended a number of bee-keepers in suits at law brought against them. His successive re-election each year gives evidence of the satisfactory manner in which he has performed the duties of his office.

In no one thing has friend Newman shown the persistence with which he follows up any matter he undertakes, more than in his fight against adulteration, and in connection with it what he so constantly calls the "Wiley lie." Prof. Wiley, with all the weight of his official position under government, perpetrated the "scientific pleasantries" that comb honey was manufactured without the aid of bees. Far and near it was copied by the papers, the professor looking on complacently at the mischief he had wrought, without offering a word to stop its course. Mr. Newman demanded a retraction, with no success, for a long time, but he kept up the warfare, denouncing the falsehood with ever-increasing vigor, using such strong language, and such bitter denunciations that one could hardly withhold sympathy for the poor professor, so mercilessly belabored. But it is probable that nothing short of such vigorous language would have wrung from Prof. W. a tardy denial of the truth of his statement, and a mingled attempt at apology and self-justification.

Notwithstanding the use of vigorous language on the printed page, in his attacks upon that which he deems unjust or false, in personal intercourse friend Newman is always the courteous gentleman. Hardly up to medium height, he is of strong build, and of active temperament. In convention he is a good presiding officer, and an easy speaker, sometimes rising to flights of eloquence on themes which, treated by others, would be but commonplace.

Let us all heartily join in the wish that Thomas G. Newman may long be continued at the helm of the good old *American Bee Journal*.

Marango, Ill., Oct. 20, 1888.

C. C. MILLER.

In addition to the above I will say that my acquaintance with the subject of this sketch began when friend Newman first assumed the editorship of the *American Bee*

Journal. A good many things were in rather bad shape when he took hold of it, if I am correct, and I was forced to admire the courteous and gentlemanly way in which he commenced to put things into shape. Any one who can not get along with friend Newman in business matters, is certainly very hard to please, unless, indeed, it is one of those queer individuals who prefer to have no sort of understanding or settlement either. During our long business acquaintance, very seldom if ever has any thing occurred to prevent a regular settlement of accounts at the end of every thirty days; and in this respect friend Newman is a good model for bee-keepers at large; for my experience seems to indicate that the whole bee-keeping world, as a rule, has a dislike for regular, systematic ways in finances; that is, for having a regular settling-up and perfect understanding *the first of every month*. Things are received that are not satisfactory, perhaps not as ordered; but some of the brethren will wait a year and then complain. It is an old adage, that "two of a trade can never agree;" and I am sorry to say that at one time it seemed to bid fair to be the rule among bee-journals. May God forbid that it should ever be so any more. Friend Newman has always stood ready to go more than half way toward amicable relations toward all the bee-journals published, so far as I know.

CONVENTIONS ET BEE-JOURNALS.

SHOULD THEY AMOUNT TO ONE AND THE SAME THING? IF NOT, WHY NOT?

ON page 933 is an item headed "Conventions versus Bee-Journals." Allow me to change *versus* to *et*, because there is no conflict. "Bee-journals fill a place that conventions can not fill, and it is equally true that conventions fill a place that bee-journals can not fill." Quite correct. "The information then furnished by the bee-journals will have an added interest" (after you've attended a convention), "and you can read very much more understandingly." True also; but with threefold emphasis is it true that you can hear the discussions at a convention understandingly after you have thoroughly read up all that is said in the bee-journals and in the bee-books. I have heard men ask questions in a convention that showed they had a poor understanding of what was going on, which questions would have been readily answered by any one who had done even a small amount of reading beforehand.

Although bee-journals and conventions are different in their uses, and both needed, I do not believe there is any great harm in trying to have a bee-journal approach somewhat in character to a convention. The familiar talk and friendly discussion, getting the views of a number on the same point—such things make the printed page quite a little like meeting our fellows face to face. So, as far as possible, I like to have every bee-journal that arrives seem like a convention; and if we could have one that should have all the advantages of a convention, with only the ordinary cost of the paper, it would be a great gain. But to have a convention modeled after a bee-journal is another

affair altogether; and if a convention *could* be made *just like* a bee-journal, that would be the end of it, for the expense of attendance would rule it out of existence. I am afraid too many conventions try to take the place of the bee-journals, and to just so great an extent lessen their value.

It might be a good thing to find out what are the distinctive characteristics of a convention that give to it its peculiar value, and then try to make the most of them. The warm grasp of the hand as we meet our brethren, and the multiplied opportunities for friendly intercourse in pairs or little groups at various times outside of the regular sessions—these no one will undervalue who has ever had the privilege of enjoying them. No printed page can give us these. If nothing more were to be had at a convention it would pay to go some little distance to attend one; but I suspect the attendance would be rather slim. The attendance at the regular sessions is, after all, that for which we go to a convention. And what is it that gives special value to these regular sessions? The time is chiefly taken up with essays and discussions. Which of these should have the preponderance? Which is more valuable, or do they stand on an equality? Could the time be wholly taken up with one to the exclusion of the other? Undoubtedly a session might be entirely taken up with essays, or entirely with discussions. I have known both kinds. How about having all essays? My good friend Prof. Cook will say that well-matured thoughts are given in an essay—hence more valuable—and he rejoices in the thought that some of his friends are coming over to his views. I wonder if he didn't misunderstand them. Well, I admit that a well-prepared essay from one who is accustomed to putting his thoughts on paper may be more carefully planned, possibly more condensed, than would be an impromptu talk. Even if every member present were capable of this, would it be advisable to have the time all taken up with essays? Where is the difference between essays at a convention and the same essays in a bee-journal? Simply that, in the latter case, you read the essay for yourself, and in the former you listen to some one else reading it aloud. If every essay-writer were a fine reader, it is possible that one might do better to listen to the reading than to read for himself. Even then there are some advantages in the latter case, for often one wants to stop and think over a certain point, or perhaps refer again to something passed over. But it is lamentably true that not one writer in ten can read aloud an essay in an acceptable manner, in which case there is nothing gained by having the convention usurp the place of the bee-journal. In case all were the best of readers, would the advantage of hearing the essays read by good readers balance the extra expense? For, be it remembered, the average cost of attending a convention exceeds many times the cost of all the valuable essays published in one of our best bee-papers in a whole year. So it seems to me we shall do better to keep each one at its best work—the paper publishing essays, and the convention having live discussions.

I know there is more to be said on both sides, and I know that all do not agree with me. I think it possible, too, that some may think it hardly worth while to fill the columns of our journals by discussing such matters. But thousands of dollars are spent every year on conventions, and it surely is

important for us to discuss how we may get the most good out of them.

C. C. MILLER.

Marengo, Ill.

Friend M., I think I agree with you exactly; that is, I shall decide that I agree until somebody suggests something that I have not thought of, and convinces me that I don't; and when we attend conventions, let us keep the matter in mind.

THE COMMON HORN-TAIL.

WHY WE SHOULD SET OUT LINDENS INSTEAD OF MAPLES.

MR. W. FULMEN sends me two specimens of our common horn-tail, *Tremex Columba*, of which he writes: "I found them yesterday busily employed stinging a Norway maple. I suppose they were laying their eggs. The one had his (her, of course) instrument inserted at least half an inch in the hard wood. Please be so kind as to give name and habits, in GLEANINGS."

This common horn-tail is nearly cylindrical, about the size of a lead-pencil, and $1\frac{1}{2}$ inches long.

TREMEX, OR THE COMMON HORN-TAIL.

The figure shows the form nicely. The colors are black, dark brown, and yellowish brown, each shown in the figure by shading. The yellowish brown is lightest; the black, darkest. The name, horn-tail, is significant, as will be seen by the figure. This horn-tail is really an auger, by use of which the insect can bore into hardest wood. This auger reaches on the under side of the abdomen more than half way to the thorax, so it is more than twice as long as it appears when viewed from the back. Thus the insect, when boring, can bear its weight on this auger. It is interesting to see them engaged in this work. As Mr. Fulmen suggests, they bore to lay their eggs. The auger, like the sting of a bee, consists of three pieces—the awl, or central piece, the auger proper, and two side pieces, which are doubtless guides or supports to the awl. The male, of course, has not this auger, and is more yellowish.

This horn-tail lays its eggs in all maples, in oak, birch, hickory, and beech. Harris says it also works on elm and buttonwood. Frequently the insect drives its auger in so deeply that it can not draw it out. I have thus caught them hanging to both beech and maple.

The larva which hatches from the eggs laid by these horn-tails is yellowish white. It is nearly two inches long, when full grown. These grubs often do much harm to our maples, as I mention in the work, "Maple Sugar and the Sugar-Bush." This is an

other reason for planting lindens for shade, instead of maples. We should suppose that such insects, living and feeding in sound hard wood, would be safe from all foes, but this is not so. We have at least two ichneumon flies that bore into trees harboring these horn-tail larvæ, and deposit their eggs in the tissues of the borers. Thus even these borers are not safe, but often become victims to ichneumon parasites. How does the ichneumon fly know where to bore? How can she know that, deep in the hard wood, the borer is working? I surmise that, by walking up the tree, she feels a tremor caused by the gnawing of the larva within. It hardly seems possible that scent can guide her. Odors could hardly penetrate solid wood. A. J. Cook.

Agricultural College, Mich.

But, friend Cook, there is just one thing I want to know about these augers: To make an auger bore, it must rotate; but the machinery in question, however, can not well rotate. How, then, does this auger work? Can't you give us a drawing of it? In our description of bee-stings the matter was lightly touched; and inasmuch as it comes in the line of the way in which bees bore holes with their sting, we think it might be profitable to have it fully described, with illustrations, in a bee-journal.

CAGING QUEENS JUST BEFORE THE HONEY-FLOW.

E. FRANCE SUGGESTS A VERY IMPORTANT MATTER.

THE bee-keeper's summer is past, the harvest is gathered, and what is the result of the season's labor? All who read the bee-papers know that the honey crop was small this year, and smaller last year. I for one don't expect a full crop next year, owing to the dry weather during August and September of this season in our locality. But after all, I individually am thankful for the small crop that we did get, and my faith in the bee-business is still good. I think there are better times coming, when we shall get our reward if we stick to the bees. Perhaps it is a good thing for us to have short crops for one or two years. The old surplus will all be worked off, prices will be kept up, and bee-keepers will be made to understand that they are dependent upon some higher power than ourselves to secure a bountiful harvest. No matter how much skill the apiarist may possess, the bees can not gather honey unless it is supplied for them to gather. The supply is beyond our control. But after all, the skilled apiarist can manage and manipulate his bees so there will be a great difference in results, providing there is a flow of honey at any time during the season, of some sort. With us we have had good honey seasons for a long term of years, and so we were able to take a little over 100 lbs. per colony of surplus until the year 1887, when we got only 12 lbs. per colony. Owing to the dry weather of 1886, the clover was nearly all killed. The year 1887 was a dry year also, but we had some rain in the fall. A great deal of clover came up from seed, but this was not advanced far enough to give us a crop of honey this year, 1888; accordingly all the honey we got last year, 1887, and this year, 1888, came from basswood. Last year we obtained 12 lbs., but not half as much as we should have so-

cured had we managed our bees as we could have done. We had 410 colonies, and obtained 4920 lbs., all from basswood, which was the only thing during the season from which it was possible to obtain any surplus. The same is likewise true of this year.

How could we have done better? I will try to explain the situation a little, and then tell how we could have obtained more honey. First, remember we worked for extracted honey. The year 1886 was a good honey season, and we secured a large crop of clover honey before the dry weather set in. Then the dry weather did not affect the basswood, so we got a big crop of basswood. We let the bees fill up their hives with basswood honey to winter on, as we usually do. After that there was honeydew on which the bees lived until winter, so their combs were loaded with honey. When winter set in they had enough honey to eat for their own use, and to feed their brood until the basswood came the next season. When the basswood opened they had the most of the honey used up, and all the combs were full of brood from top to bottom, and no place to put any honey. All they could do was to fill the cells as fast as the brood hatched. The basswood lasted 12 days, and it took 21 days to hatch out all of the brood. It was positively necessary to leave honey in those combs to winter the bees. Could we safely take out any? Yes, we could extract for a week, and give them time to fill the combs that we emptied; and if we whirled the combs pretty hard, perhaps we could throw out some of the younger brood and give the bees a chance to fill their places with honey. We concluded to do that, and did do it; but as it took a week to go over the bees we got but very little honey the first three or four days. We got out a great deal of young brood, and that gave more room to store honey. Then as the older brood hatched, that gave room to store honey. By the time the basswood flow came to an end, the bees had enough honey stored to winter on, besides the little we took out.

Now, I am aware that I have introduced a strange idea in throwing out brood on purpose to benefit the bees; but under the circumstances it was the best thing we could do, as the hives were crowded full of bees. The combs were full of brood, and no place to store honey. If we had had on hand a large quantity of empty combs, then we could have made good use of them; but we did not have them, and so we had to do the very best we could. How could we have done better, and got more honey? By simply caging the queens ten days before the basswood flow commenced; then the brood would have been about half hatched out by the time the flow commenced, and all would have been hatched by the time the basswood ceased. The queens could then have been liberated. The bees would not have tried to swarm when the queens were caged. All queen-cells should be destroyed, and ten days from that time they should be destroyed again. There would then not be any attempt to swarm until the queens were liberated and some brood started, and not then if the honey-flow were over. Why did we not do it, and secure more honey? We did not think of it in time, as we had never been in the same fix before. But we have been partially in the same boat this year again. We started in this season with 431 colonies, and had to feed about 500 lbs. in the spring to get the bees through to clover, from which they gathered just

about enough to keep them in good breeding condition. We saw that there would be a fair yield of honey from basswood, so, as nearly as we could guess, about ten days before the basswood opened we caged 150 queens, to test our last year's theory. The result was, we got 11,830 lbs. of honey—about 27½ lbs. average, and I should think that ¾ of that honey came from the 150 colonies where the queens were caged. Remember, our average last year was 12 lbs. We came to the conclusion that we should cage queens again to increase our honey crop. We think it is a good thing if it is rightly managed, any year.

The cages we used were made of wire cloth, about 3 inches long, ¾ inch wide, and ¾ thick. One end was plugged with a wooden stopper, ¼ inch long; the other end was just pinched together after the queen was in the cage. The cage containing the queen was hung by a fine wire between two combs in the hive from which she was taken. The bees in the hives feed the queens in the cages. Out of the 150 queens so caged, three died; 147 were alive, and in good laying condition. Some of the cages had eggs in the lower end, ¼ inch deep in the bulk—more than the size of the queen. I don't know whether the bees made any use of the eggs or not, as we kept one or two combs of young brood in the hives, from other colonies; but I know that bees will sometimes take eggs from a caged queen, and raise queens from them. I don't think they will use them to raise workers to any extent. How long did we keep the queens caged? About 20 days—10 days before the basswood opened, and 10 days after. We destroyed all queen-cells when we caged the queens, and again in 10 days we destroyed all queen-cells. After the queens had been liberated about a week we examined all the bees we had, to see if all had laying queens, and found all the queens that had been caged were laying nicely. Now, I don't want it understood that I advocate the caging of queens, except under certain conditions. When one has all the bees he wishes to keep, and wishes to prevent swarming, *then* he should cage the queen—after the colony is very strong and about ready to swarm. Of course, the queen-cells must all be destroyed. We have often caged a few queens, but never as many in one season as we did this last one.

E. FRANCE.

Platteville, Wis., Dec. 15, 1888.

The idea of caging queens at a certain time in order to increase the honey-yield, comb as well as extracted, has been recommended and practiced to some extent for a good many years. Some have claimed that caging queens would put a stop to honey-gathering, or, at least, to a certain extent; but my experience has been that, where the queen is removed entirely, the bees ceased work. Leaving them caged in the hive as you have done, however, would probably make little if any difference with their activity as honey-gatherers. Now, in case there had been an unexpected flow of late fall honey, might not your experiment have resulted in a big loss? As our business has been for years selling bees by the pound, it has been a hard matter for us to accept the idea of repressing brood-rearing in any way; but as you state it, it seems to me very likely there might be a positive gain in the amount of honey secured, and a positive

saving in regard to the amount of sugar that must be bought for winter. We should be glad to hear of the experiments of others in this matter.

RAMBLE NO. 10 CONTINUED.

A NOVEL METHOD OF PEDDLING HONEY.

UNCLE JOHN runs his colonies for the production of comb honey. His son Cyrus, not having much love for the busy bees, attends to the farm, and makes gardening a specialty. The products of the garden and the apiary find ready sale at hotels and to the boarders themselves; for about 20 miles from the head of the lake, nearly every point and island has a hotel or several cottages upon it. For instance, Ripley's Point has a hotel—Horicon Lodge—and a dozen cottages. During the camping season these must be supplied with vegetables, etc. Mr. Cyrus A. supplied a few of these resorts, at first with a row-boat; but seeing an opening for a little expansion in the business he fitted up a boat with a kerosene-engine. This pretty little craft will carry 17 persons, or over a ton of supplies. Every Wednesday and Saturday the boat is loaded with a miscellaneous cargo of potatoes, onions, celery, and every thing from the garden; and last, but not least, a few crates of honey. The voyage is then made from point to point, and the entire day is spent in disposing of the cargo.

PEDDLING HONEY WITH A STEAMER.

Comb honey finds ready sale at 16 cts. per lb. Mr. A. was selling his honey off nicely at 15 and 16 cts., when, upon his next trip, he found the market demoralized, and the bottom knocked clean out by an outsider running in a load of honey and selling it for 10 or 12 cents per lb. In consequence he is strongly in favor of co-operation, or the buying of all of these stray cheap lots, or, what would be better, the purchase of their entire stock of bees.

Extracted honey can not be sold at any price, owing to suspicion of adulteration. Even comb honey in regularly filled sections is looked upon with suspicion; and city people, before purchasing, want to prod a jack-knife into the center of it to test it.

While extracted honey can not be sold, there is a call for maple syrup, and it will be purchased and greedily eaten, and hardly a word be said about its purity; and we all know that maple syrup is adulterated as much if not more than honey. Is honey held more in suspicion because the busy bee and the production of honey calls forth sensational lies, and syrup free from it, because the noble maple can not be so much lied about? Another question that is beyond my solving is this: Why will people use some articles of diet that are grossly adulterated, and know it, and refuse articles like honey, against which they have only a remote sus-

picion? The little steamer is, however, on its mission every summer, and we hope it will exert an educating influence on all city people who purchase what it pleases them to term wild honey?

On Tuesday our visit drew to a close. We cast lingering glances at old Buck Mountain, with its huckleberry paradise; at Shelving Rock, with its rattlesnake dens; at Tongue Mountain, noted for deer and the deer-slayers; at the placid waters into whose pure depths the eye can penetrate 20 or 30 feet; the islands, fairylike in their beauty; the boats, with their suggestions of pleasure and exercise; we could scarcely tear ourselves away from so many attractions, and the Rambler would willingly rest from his wanderings, and build a log hut under the sheltering trees, and, 'rusee like, spend his days in hunting and fishing.

Our last repast in Camp Andrews was a picked-up dinner. The most prominent object on the table was the doctor's medicine-box, with 500 bottles, more or less. It was a terrible-looking instrument of destruction.

The only accident of note was a thrilling adventure of Mr. Lockhart, who rushed in one dark night, averring that he had been knocked down by a burglar. We prospected with lanterns, and found he had tumbled over a big boulder. It is a mystery how people's imagination will run away with them. Another was a skillful star scene, indulged in by the Rambler. He tried, and succeeded in sitting down in the lake.

The pleasures of the visit will be long remembered; and the many kind favors bestowed on the Rambler by his fellow-campers and members of the family, I trust can some time be returned; and that other bee-keepers can some time enjoy a week at Lake George is the earnest wish of the RAMBLER.

LOT'S WIFE.

DEACON SMITH DISCOURSES ON THE ELEMENTS NECESSARY TO SUCCESS IN BUSINESS.

DEACON SMITH was on the winning side in politics this year. He is therefore more loquacious than ever, and more genial, if that were possible. He has spent several evenings at our house since election. He brings "Mirandy," and Mirandy brings her knitting-work. Our apple-barrel holds out yet, and the bee-journals have not lost their interest, although truth compels me to state that they were only secondary during the heated campaign.

The deacon's teeth are a little poor; but our Wealthies are in their prime now, and he is obliged to acknowledge that they are "most as good as the Greenings of York State."

The last evening he spent here, the deacon got to talking about the elements necessary to success in business.

"Now, there was Lot's wife," said he; "what a shining example she was of how not to do it!—not that I blame the poor tired woman for looking back upon the scenes of her childhood. Anybody could have forgiven her for that. But Moses was too busy looking after the wayward children of Israel to give us her full history, and you see she wasn't worthy of a page or two in the Biblical record. He only mentions her, as the preacher does the text, to give point to her instability of character. Did you

ever think of it? She hadn't even a name in the book. There's Sarah and Rebekah and Esther and Ruth, and a host of other noble women who have blessed the earth ever since they lived. But she was Lot's wife—that's all. If she had been a woman of character, do you think she would have been consigned to everlasting nothingness in that kind of style? Even Jezebel got more distinction than that.

"Just imagine what a rattling there would be among the dry bones if Mirandy should die, and I should put up a respectable monument to her memory with this inscription: 'The late Mrs. Smith,' instead of saying, '*Hic jacet* (here lie) the mortal remains of Amelia Mirandy Sunnyweather, the late consort and worthy helpmeet of Uriah Smith, a woman who never turned her back on a duty unperformed.'

"If you will read between the lines you will discover that Lot's wife was one of those weak-minded, changeable persons who never have an object in life, and are blown about by every wind of doctrine. When Lot started from Sodom she thought she loved him above every thing else, and she'd share her fortunes with him. But when she got tired, and had blistered her feet on the sand, she thought, 'What a fool Lot was to believe what those men told him! I guess I'll go back.' So she turned back to the luxurious city she had left, thinking perhaps that her husband would soon follow suit. You know the rest.

"Now, that's the trouble with a great many men in this world. They don't know what they are here for. They haven't any purpose. Like a lost dog they will follow the first emigrant wagon that comes along, if the driver only whistles.

"Perhaps they are farming. Things haven't gone first rate. The price of hogs has gone down, and cholera specific has gone up. Along comes a white sail with the magic word 'protected wool' on. The hogs are sold, given away, or run into the sea. They are only swine, any way. But sheep are high. By the time he gets fairly started—has learned how to keep the wolves off by day and the dogs by night, how to save the lambs in spring and the old ones from foot-rot in the summer, he discovers that Texas and Australia can raise wool cheaper than he can, and that sheep-raising is not so profitable as he thought. So he sells his sheep at a sacrifice, and invests in booming cattle. It's the same old story—buying at the top and selling at bottom prices. Old age creeps on apace. By the time he has run the gamut of the industries he is ready to vote with Solomon that variety and vexation of spirit is the common experience of the farmer; whereas, if he had stuck to some one thing he might have compelled success.

"There's neighbor Jones. He bought a lot of bees a few years ago when bees were high and honey ditto. He thought that was the highway to wealth and happiness. He put a good deal of money into the business—a good deal more than there was any use of. He didn't know any more about bees than a sand-hill crane does about astronomy. He only soared among the clouds. The first winter he lost heavily. The next summer his profits were so fine he couldn't see them. Last year wasn't much better, but he got a good deal of experience. But he got disgusted with them, and put them all up at auction. I bought the whole outfit for a song. Now, I know there isn't money in bees every year.

They don't make honey. It's got to be in the flowers, or the bees can't get it out, but I'm bound to stick till the Lord sends the early and latter rain, according to promise. It's the only thing to do. You know what Poor Richard used to say: 'A rolling stone gathers no moss.' After a man has got every thing fixed to keep bees, it's the foolishlest kind of folly for him to surrender and admit he is licked because there happens to be one or two bad seasons. There's nothing in this world that I know of that is always on the high road to prosperity without work, and sometimes there's a deal of waiting too." Reported by— EUGENE SECOR.

Friend Secor, you are lucky in having Deacon Smith for a neighbor. Don't mind the apples. When he gets a going, just give him plenty of rope, especially if he exhibits as much wisdom as he has in the above. While in California I was greatly impressed with the very idea the Deacon has brought out. When 200 lbs. or more of nice honey was obtained per colony, a few years ago, a great many started in the business. Some of them have held on to the bees for a couple of years; but at the present time a great many are deserting their bees, or are offering to sell them for a mere "song," as you express it. Now, I do not mean that one should keep on devoting his whole time, and making outlays, while the seasons are so unpropitious that there is little or no income. I believe it is prudent to stop outlays, and let the bees stand still while there is nothing in particular to be done with them, keeping a careful watch, of course, that they do not get out of stores and so starve to death. It would be very strange indeed if no more crops of honey were to be secured, such as we had five or ten years ago. If we talk with men in most kinds of business, especially those who raise crops, you will find a good deal of the same state of affairs. It is terribly expensive to learn a trade, and rig up for the profitable working of any kind of business; and he who abandons, as soon as or shortly after he has got ready for business, must expect to do it at a great sacrifice. Work at something else if you choose, while your regular business can not be followed; but do not let things go to ruin, or swap them off hastily.

A GOOD QUESTION.

DO BEES BUILD HEAVIER COMBS AT ONE TIME THAN AT ANOTHER?

AS C. C. Miller had made some observations on the subject as above, we sent the following to him:

Friend Root:—On page 803, you and J. A. Golden fail to understand why bees build heavier comb at some times than at others. I have noticed for several years, that, during a rushing flow of honey at any season, and from whatever source, whether clover, buckwheat, or aster, the comb is invariably thin and light; but when honey comes slowly, the combs are heavier. White clover was almost a total failure here, but buckwheat and asters yielded fairly well. BURDETT HASSETT.

Howard Center, Howard Co., Iowa.

Mr. Miller replies as follows:

I do not know that it is of practical importance to know why and when bees build heavier or lighter comb; still, it is a matter of interest, and a practical bearing may attach to a subject, although such practical bearing may not appear on the surface. I have some doubts as to the cooler weather of fall making bees slower about drawing out wax, thus making the comb heavier. Bees keep up the heat in the cluster, summer or fall; and if the wax is soft enough to be worked, I suspect they will work it thin one time as well as another. But it is not unreasonable to suppose that, like the human family, bees will be more lavish in the use of any article which is plentiful. It is not likely that the secretion of wax is in exact proportion to the amount of nectar gathered daily. Suppose a heavy flood of honey is being gathered. The bees will secrete wax enough to take care of it, and this secretion is a matter of time. It can not be started or stopped in a minute. When they stop gathering honey at night, the manufacture of wax keeps right on through the night; and if a heavy rain should occupy all the afternoon it is likely the same amount of wax will be secreted as if the bees worked in the field all day. And I see no reason, if the bees work all day in the fields, why there should not be just as much wax secreted, whether the field allows a bee to gather a load in 24 or 40 minutes. In other words, there should be no difference in the wax production, whether the bees store two pounds a day or twice as much. But if the wax is secreted, it will be used in some way, and I suspect that bees are likely to build thicker combs if they have a double supply of wax. If this be the case they might be expected to make thicker cell-walls when the harvest begins to wane.

Thinking this matter over last evening I said to myself, "If your theory is true, facts ought to sustain it. Last summer the yield was very slow, and you ought to find very heavy comb." So I got a section of honey out of the cupboard to examine. Sure enough, it appeared to me the cell-walls looked thick; but then, I had no other comb to compare it with. I cut out a cubic inch, as nearly as I could estimate it, and chewed it. The resulting wax I rolled into a round ball, and it measured just about half an inch in diameter. That seemed to me like a good bit of wax; but, as before, I had nothing to compare with. Friend Root, try a cubic inch of honey, perhaps of two or more different samples, and tell us how much wax you get from it. Here is another fact that is confirmatory, so far as it goes:

Last summer the bees made more trouble than I remember ever before, in making bits of white comb where not wanted. In a good many instances they made little sheets of wax arise perpendicularly from the separators, as if trying to increase the width of the separator. They also plugged up crevices as if with propolis, only they used pure white wax. So far as I could judge by looking on, the bees were busy every day; but a total crop of less than a ton from 135 colonies shows that the daily yield must have been small, requiring little wax, and allowing plenty for thick cell-walls and an overplus to be used as bee-glue. By the way, in every lot of bee-glue I think more or less wax will be found on melting.

SIZE OF APIARIES.

The item on page 933, with its comments, "Advantages of Small Apiaries," reminds me that it is not safe to base general conclusions on one or two data. A small apiary of 12 colonies gave almost enough

surplus to supply the deficiency of" a larger apiary of 60 or 70 colonies. Now, friend Weckesser, the small apiary may have given the surplus just because of the few colonies; but the facts you state by no means prove it. The past summer my Wilson apiary had about three times as many colonies as the Belden apiary; but the *larger* apiary "gave almost enough surplus to supply the deficiency of" the smaller. But that doesn't prove that the larger number made the yield per colony greater. The Wilson apiary probably had a better field to work on, and probably your 12 colonies had a better field than the home apiary. I do think, however, that in general a small apiary will do better than a large one, just because there will be times during the season when the harvest is so light that even a few colonies overstock the locality. But the difference may be so little that I think in general I would not start an out-apiary till my number exceeded 100. So I agree with the comments.

Marengo, Ill.

C. C. MILLER.

Friend Miller, your explanation seems to be the more reasonable one. It is a fact, is it not, that bees do at times secrete more wax than they can profitably use, and that these scales are sometimes found on the bottom-board? Friend Hutchinson avers that, in consequence, too much foundation is used, and that this surplus of wax scales goes to waste. According to your request, we tried two or three samples of honey. As the flow of nectar in California is considered to be very rapid, it is reasonable to suppose that California combs would be lighter than combs to hold an equal capacity made here in the East. We accordingly selected a section of California honey well filled out, and of snowy whiteness. From this we took two cubes of honey. From each the resultant wax made a sphere only a *quarter* of an inch in diameter. Of course, this wax was pressed together into a solid ball. We next selected a section of honey which had been filled out during the last season in our own locality, when the yield of nectar daily was very small. This section was travel-stained, and there was a number of cells not capped over. From this we took a cube of honey, chewed it, and obtained a wax ball *half an inch in diameter*. As will be seen, the diameter of the latter was twice that of one of those from the California honey. Therefore the *volume* of wax would be just about eight times as much. From this it might be argued that bees will use *eight* times as much wax in comb building during a *slow* yield as they will in a *rapid* yield. These proportions may not and probably will not hold true in all cases; but as the experiment can be so easily tested, we hope our readers who are interested in the matter will do so and report the result, noting carefully whether the nectar was coming in rapidly or slowly. Now, friend M., you start out by saying that you do not know that there is any practical importance in this matter; but you intimate that a practical bearing *may* attach to it. Well, it *may* be this: When honey is coming in *very rapidly*, the bees need full sheets of foundation; when it is coming in *slowly*, narrow starters will answer just as well and perhaps better. If this be true, may it not be possible to save foundation, and, con-

sequently, money? Again, if bees do at times build heavier combs than at others, may it not explain why there is sometimes present the objectionable "fishbone," and that at other times it can not be detected?

HEADS OF GRAIN FROM DIFFERENT FIELDS.

CARRYING BEES INTO THE CELLAR; DOOLITTLE'S AND ROOT'S INSTRUCTIONS OBEYED.

I WISH to thank you and G. M. Doolittle for that article in Nov. 1st GLEANINGS, in reply to my questions on placing bees in the cellar. GLEANINGS arrived here about four o'clock, Nov. 7; and after reading the article referred to I decided to set the bees in at once, as it was looking like rain, the weather previous having been remarkably fine. There were 82 in all, and we carried them in, some before dark and some after, and found no difference. In your remarks you seem to think the bees would be more apt to get out of the hives when the bottoms are removed. Now, if you mean while carrying them, you are wrong; as the bees seem to get confused when they run down and can't find their floor, and very few will fly out of their hives. If you mean that more bees will get out of the hives in the cellar, you are right; but I think we want them to, as, when a bee becomes so weak as to fall from the cluster, it is better out of the hive, as they will sometimes pile up in the bottom and make a very bad smell. I did not place my bees as Doolittle does, as I had not room. I simply placed two scantling about a foot from the ground, and set a row of hives on them, then two more, and so on. I think it would be a good idea to have the scantling supported independently of the hives, so any hive could be removed if necessary.

Alvinston, Ont., Can.

W. E. MORRISON.

SOD HOUSES FOR WINTERING BEES, AND FOR RAISING PLANTS AND CARP.

Please send me some Grand Rapids lettuce. I have a greenhouse, and am raising plants. I have built a water-tank 5 feet deep, 8 feet wide, 32 feet long, in which I have about 400 carp. I have three-fourths of the tank covered with floor, with a good sod house built over it. I have a pipe running into it, with a pipe for the water to escape into a hatching-pond about four rods square. My carp are doing well, and so are my bees. You remember I wrote to you last winter about keeping my bees in a sod house. Well, last spring I thought I would experiment a little, so I built a sod wall, and made spaces in the wall, facing the south, to set the hives in; then I took two boards, a little longer than the spaces, and took old barrel-staves and nailed to the boards for cages. I am well satisfied with the arrangement so far. When I wish to work with a hive I can just remove the cover, as each has a separate one. I have 39 colonies in hives, and one I took from the woods, from a hollow tree.

R. F. LOOMIS.

Indianola, Neb., Nov. 21, 1888.

THE COTTON-TREE OF THE SOUTH A PRODUCER OF HONEY.

IN GLEANINGS, June 15, a man in Texas asked you some questions. Among others was this one: "Is the cotton tree good for honey? You did not know,

but you stated that the cottonwood-tree of the North and West was not a honey-producing tree. The name cotton-tree is a local, or common name only. The proper, or scientific name, is *Paulownia*. It grows as large, or larger, than a big apple-tree, with much the same form. It blooms early in the spring, before any leaves appear, and is remarkably fragrant. One large tree will scent or perfume half a dozen town lots. It is raised principally on account of its strong perfume and dense shade. Its flower resembles a purple Jimson (Jamestown) weed, except it is only half as long. In regard to its being a good honey-producing tree, I can't say any thing further than this: Bees work on it just as fast as they do on an apple-tree in Ohio when in full bloom. But few people here know its right name. I asked a great many before I found out, and Dr. Brantley, one of your subscribers, gave me the true name. The doctor is well posted on nearly every thing, and is one of the best conversationalists I ever met.

Atlanta, Ga., Dec. 15, 1888.

JOHN BARFORD.

WATER IN A BEE-CELLAR, AND HOW IT MAY BE SUPPLIED.

I winter most of my bees in the cellar, and generally with very good success. I have just built a cellar especially for the purpose, in which 151 colonies are wintering. They are exceedingly quiet, which I consider the best proof of perfect wintering in a cellar. Having had positive proof of the benefits of water in the cellar several years since, I wanted a living spring in my new cellar; and as we found none while digging it I managed to get a cheap artificial one by digging out at one corner, thus. The small room, or projection to the cellar, takes in my pump-pipe (it is a drive-well iron pump). The supply of water for the cellar is simply the waste which spurts out of the vent-hole in the pipe; and as this well furnishes all the water used by two families, besides several head of stock, there is a large quantity of water which passes out of the pipe into the cellar. The cellar is under a part of the dwelling-house, and the pump is at one end of a porch. It has a stone wall full depth, and is lathed and plastered overhead. The surplus water passes off through a drain. I expect to utilize the little room for milk and butter in warm weather, letting the water pass around the milk-dishes, etc.

O. H. TOWNSEND.

Alamo, Mich., Dec. 11, 1888.

SMALL SECTIONS, AND HOW TO MAKE THEM OUT OF WOOD SEPARATORS.

Having read of the Rambler's troubles with the Harmer 2-oz. section, I will tell him, and others who may be interested, how I made 200 or 300 last spring.

Having bought of you a lot of wood separators I took some of them, cut them into lengths of $7\frac{1}{4}$ inches, and then cut the lengths into strips $\frac{3}{4}$ inch wide, and marked them off like this.

Now take a sharp-pointed knife and cut the cross-lines partly through and you can fold them very easily, and they will fit into the frames all right if cut accurately. In folding I put a drop of glue where the ends meet; but perhaps a bit of well-gummed paper would be better; it certainly would not be so sticky to handle as glue is. I was not very successful in getting them filled, but I think the

trouble mostly was due to there being no honey to gather, as I got but 300 lbs. of comb, and no extracted honey this year. I will try the little sections again this coming summer.

O. G. JOSEPHANS.

Owosso, Mich., Dec. 7, 1888.

HONEY GRANULATING.

I read in GLEANINGS somewhere of the spraying of honey in extracting causing, or at least hastening, granulation, in something the way that stirring sugar syrup when making taffy will cause it to granulate. When the stirring is slight, the granulations may not commence until the taffy is sold, and sometimes several hours afterward. I had practical proof of this fact this fall. When taking off my honey I cut out the unsalable sections and filled a jar with them, to sell in bulk to home customers. After emptying the jar a few days ago, I found the droppings not granulated in the least, while honey of the same kind, extracted at the same time that this was cut out, and though in tight cans, and capped up, was granulated so much it could not be poured out without warming; and some in an open lard-jar was solid, while the droppings from the uncappings in another jar were granulated but little; this was all late honey, mainly from Spanish needle, which does not granulate so readily as clover honey.

B. A. RAPP.

Chillicothe, Mo., Dec. 8, 1888.

FOUL BROOD IN NEW ZEALAND.

The Langstroth hive is the one in use in New Zealand by all advanced bee-keepers, and is found quite sufficient protection without chaff packing, to winter on summer stands, owing to the mildness of our climate. I noticed a report in a late issue of GLEANINGS (July, I think), that foul brood is very troublesome in the North Island. This I believe is correct, but it is not so prevalent in the South; indeed, we much doubt if the true foul brood exists here at all. It is a very mild form of the disease with which we are acquainted, and readily yields to proper treatment.

R. E. D'O'LY.

Dunedin, N. Z., Nov. 1, 1888.

ARE QUEENS INJURED BY SHIPPING?

I read with no little interest friend Doolittle's article on page 749. It is just so near my own experience in handling and shipping queens, that I am fully persuaded, from practical trial and application of many of the circumstances mentioned therein, that friend Doolittle is *nearly correct*, while our friend Chas. Dadant, on page 846, is very much in error, I am sorry to say. It would be furthering my interest very much if I were able to sustain his assertion: "The shipment, by mail or express, does not deteriorate the laying of a queen, * * * even when she is taken from a full colony during the height of the laying season." Nearly every *prolific* queen that I have ever sent out from a full colony in the height of the laying season has been more or less a failure, ever afterward, as a layer. Why this was so, I am not able to say, though it may be caused in a variety of ways. A queen, when once partly starved, chilled, or overheated, is never worth any thing as a laying queen, though she may lay a few eggs, and live a year or two. A queen taken from a full colony in the laying season, and full of eggs, may be damaged by the difference in the temperature while in that state, as much as by the stoppage of laying in the regular order. No one, I hope, will say that it does not damage man to eat at ir-

regular intervals. Which of the two is the more delicately constituted, and liable to injury by a slight diversion from regular order of life—the laying queen or the human stomach? I want to emphasize the fact that a queen that is but a spare layer is just as good to breed from, and better than one that is an excessive layer. And, again, that queens taken from a nucleus hive are more profitable to the purchaser than those taken from a full colony in the height of her laying season.

ABBOTT L. SWINSON.

Goldsboro, N. C., Dec. 4, 1888.

With the large number of queens we annually send out by mail, it is strange that we have not noticed, or, rather, received, many complaints of such deterioration in said queens. There may be an occasional instance that seems to point that way; but that such cases may be frequent is not a matter of our observation. If you and friend Doolittle are correct (and you may be to a certain extent), why is it that we have never heard more frequently of such failure of egg-laying before? Now, it is just possible that your last sentence explains the difference in our experiences. Although our cells are raised in full colonies, the queens, as a rule, are reared in nuclei.

BALLING QUEENS; REFUSING TO ACCEPT CELLS.

Last spring, a year ago, I bought a queen from Dr. Brown, Augusta, Ga. She proved to be a fine layer, and purely mated. Last month I noticed the bees balling her. I smoked them well and closed the hive. Now they have a black queen. How did they get her, and why did they destroy their queen? In Italianizing I had colonies which would not receive queen-cells nor build one when given eggs, although they had been queenless for 10 and 12 days. Is not this unusual? In one of my colonies I often hear a noise resembling the growling of an opossum. You can hear it some 12 or 15 paces off, yet I can find nothing wrong. What do you suppose causes it? D. C. MCCAMPBELL.

Harmontown, Miss., Nov. 27, 1888.

Friend M., it is hard to assign a reason why bees will at times ball a good fertile queen. Sometimes they will attack one as soon as the hive is opened—indeed, the disturbance is what causes them to behave so unseemly. As a usual thing, under such circumstances, if the hive be closed immediately the bees will let the queen alone, though it is our practice to blow a little smoke in at the entrance. In the instance you give, the balling resulted in the death of the queen; and her successor, it seems, it was a black one. At certain seasons of the year it is difficult to get colonies to accept cells given them; but if the bees are actually queenless, beyond any question, we feel pretty sure they will accept eggs and raise cells. We should incline to the opinion that the colony you mention had some sort of a queen, probably a fertile worker. The only thing to do is to scatter the brood and frames throughout the apiary. When a colony apparently queenless refuses to raise cells we generally come to the conclusion that they have fertile workers, and a careful scrutiny of the combs generally confirms this conclusion. — Unfortunately, we don't know what an "opossum's growl" sounds

like; we therefore can form no conception of what that peculiar noise is which you notice among your bees. During the honey-flow there is a low hum that can be distinctly heard several feet away.

NOTES AND QUERIES.

STATISTICS.

ALLOW me to say that I am highly pleased with the Honey Statistics in GLEANINGS. I think that that alone should be worth a dollar per annum to many bee-keepers. I see by the latest statistics that friends Nebel & Son, of High Hill, Mo., are away ahead of us other fellows here in Missouri on the average crop of honey secured this season, and that with a large number of colonies, if I am not mistaken. How is it, friends, have you a better location, or do you know better how to manage the bees? S. E. MILLER.

Bluffton, Mo.

BEES AND FRUIT.

I notice a complaint in a recent number of GLEANINGS, regarding bees working on raspberries. I have had the same trouble, the bees being so troublesome as to almost drive away pickers.

Nichols, Conn., Dec. 13, 1888. H. P. NICHOLS.

A QUESTION FOR OUR "SALT-WATER" READERS.

What is the best paint for bee-hives in a salt-water locality—pure lead, zinc, lead and zinc, or some other kind of paint? A. B. MASON.

Auburndale, O.

[Will some of our readers located near salt water please answer? But why should proximity to salt water make any difference?]

APPLE-TREE SILK-MOTH.

Prof. Cook:—I send you by mail for identification, the pupa of some large insect found adhering to the limb of a plum-tree. Please report through GLEANINGS. W. D. ALLEN.

Kosse, Tex., Dec. 17, 1888.

Prof. Cook replies:

This fine large cocoon contains the apparently healthy chrysalis of our apple-tree silk-moth, *Platysamia Cecropia*. Next June there will come from this a large beautiful brown moth. A. J. COOK.

FEEDING EXTRACTED HONEY.

I wish to feed my bees honey for winter stores. How shall I do so, so as to have it not granulate in the combs? R. H. SHIPMAN.

Cannington, Ont.

[Feeding back extracted honey is rather unsatisfactory. It is difficult to prevent granulation in all cases. At the price honey is now, we would not think of feeding bees with it. By all means, feed sugar syrup well cooked. It makes a much better food, and if you make the syrup rightly you will have no trouble about its crystallization.]

HUTCHINSON'S PLAN ON EMPTY FRAMES; HEDDON'S NON-SWARMING PLAN.

I have tried Hutchinson's plan of hiving on empty frames, and failed. I have tried Doolittle's plan of hiving in contracted brood-chambers, filled with empty combs, combined with Heddon's plan to prevent after-swarms, by hiving on the old stand and removing old hive the 7th or 8th day, and I believe it superior to any non-swarming plan I have ever heard of for surplus honey. BENJ. A. RAPP.

Chillicothe, Mo., Nov. 9, 1888.

SOMETHING FROM THE AFRICA MISSION.

GLEANINGS has come to this mission regularly for two years. Native honey abounds in all localities; in nearly every tree you see large bark boxes put there by the natives, and many of them are full of honey. From 75 to 100 tons of wax is shipped from this port every year to Europe.

E. H. RICHARDS.

Mongwe, Inhambane, E. Africa, Oct. 20, 1888.

JAPANESE BUCKWHEAT A SUCCESS.

I got 2 lbs. from you last spring; sowed it on 20 rods of good ground. I harvested $7\frac{1}{2}$ bushels of nice buckwheat. Bees worked on it the same as on other. They worked sparingly on goldenrod; they worked very industriously on pridedweed. You could see from 4 to 12 on one head. They seemed to be crazy for it when in bloom. I suppose it is one of the goldenrod family. Bees got honey enough to winter on, and some swarms gave considerable surplus, mostly from basswood.

Chardon, O., Dec. 10, 1888.

W. MCBRIDE.

REPORTS ENCOURAGING.

FROM 36 TO 60, AND \$250 WORTH OF HONEY, SOLD PEDDLING.

THE first of May found me with 36 colonies, some very good and some very poor, 8 of which number were so weak that it took them all the season before they got built up to good swarms. From the 28, good and fair, I sold honey, both comb and extracted, to the amount of \$250. I have a little over a barrel left on hand now. I increased them to 60 good swarms. They are in good shape, with plenty of honey to last them till fruit blossoms.

PEDDLING HONEY A SUCCESS.

I sold most of my honey in my home market. I had some friends in a little town 8 miles from my place, and my wife and I were going to see them. I told her I would take some honey along, and may be we could dispose of some. We took about 100 lbs., both of comb and extracted. It went like hot cakes; and the consequence was, I made 6 trips and sold \$140 worth in that town. M. M. RICE.

Boscobel, Wis.

FROM 8 TO 16, AND PLENTY OF HONEY.

Last spring I had 8 colonies, and increased, by dividing, to 16. I had plenty of nice section honey to supply my table. I have raised and introduced Italian queens into each colony.

D. C. MCCAMPBELL.

Harmontown, Miss., Nov. 27, 1888.

FROM 50 TO 80, AND 800 LBS. OF HONEY.

I commenced in the spring with 50 colonies of bees, and they increased to 80. I got 800 lbs. of honey. I know the most of them had each nearly 100 lbs. left in the hives to winter on, because for the one that made comb honey I left all in the lower box, from 8 to 12 frames, almost solid full of honey. I clip all of my queens, and then let them swarm. I think this is much better.

Seneca, Kan., Dec. 5, 1888.

M. A. WILKINS.

FROM 30 TO 40, AND 1200 LBS. OF HONEY.

I began the season with 30 swarms—25 fair and 5 weak. I increased to 40, and took a little over 1200 lbs. of comb honey; 4 colonies did not give a

pound. I sold at from 14 to 18 cts. per lb., in Detroit. I sell all my unfinished sections that weigh not less than 6 oz., and so on up to 12 oz., some being wholly unsealed, and I find ready sale at from 8 to 12 cts. per lb. I think it better than keeping them over.

BENJ. PASSAGE.

Stark, Mich., Dec. 14, 1888.

FROM 30 TO 70, AND 1000 LBS. OF HONEY; ARTIFICIAL PASTURAGE; ALSIKE (CLOVER FOR BEES AND STOCK).

The honey-flow in this locality has been bountiful the past summer, and those who had their dish right side up caught the golden harvest. My bees did as well as could be expected, considering the amount of care given them. From 30 colonies, spring count, I received about 1000 lbs. of honey in 1-lb. sections, and increased to 70 colonies; and I think if I had hived every swarm that issued I should have had 100 colonies at the close of the honey-flow. One colony of Italians first swarmed out. This was on June 1st, and it made 49 lbs. of clover and 24 of buckwheat honey in 1-lb. sections, and they had their brood-combs well filled for winter besides. In providing pasture for my bees I had 10 acres of alsike, 10 of Mammoth, and the pastures were white with white clover; and $\frac{3}{4}$ of a mile from my apiary were basswood-trees and 40 acres of buckwheat, where the bees could go if they wished to, and they did gather so much buckwheat honey that it is hard to get 10 cts. per lb. for nice 1-lb. sections. White-clover honey sells readily at 15 cts. per lb. in 2-lb. sections.

I cut my alsike clover, and had it thrashed, and got 8 bushels of very clean seed. I shall depend upon the alsike clover hereafter, not only for bee-pasture, but also sheep-pasture and for seed. On one side of my sheep-pasture there are three acres of alsike clover. It was sown 4 years ago, in the first part of the season. The sheep feed on the other portion of the pasture; but when the other portion gets short and dry, the sheep run and put their noses into the clover, and it shields them from the gad fly, and gives them good feed also.

I have 35 swarms in the cellar and 10 in A. I. Root's chaff hives, on their summer stand.

L. N. CHAPMAN.

River Falls, Wis., Dec. 12, 1888.

REPORTS DISCOURAGING.

A POOR YIELD.

I MADE preparations last spring for a good crop of honey, and received only about 140 lbs. of fall honey (in comb, no extracted), as surplus, which sold for $12\frac{1}{2}$ cts. per lb. to apply on a grocery bill. You see the bee-business has not been very profitable for me the past season, considering that I ran over 200 colonies for honey. I had only 15 new swarms during the season. I am not one of the class who can get a crop whether it is in the blossoms or not.

O. H. TOWNSEND.

Alamo, Mich., Dec. 11, 1888.

ALL LOSS.

There has been a failure in the honey crop in this locality for two seasons. When we figure the profit and loss, it's all loss. As I read in GLEANINGS recently, I hope for a "whopper" next year.

Damascus, O., Dec. 8, 1888.

EVAN SHREVE.

WINTERING NICELY.

Bees are wintering nicely so far here. It was a very poor season; they did not gather enough to winter on.

CHARLES SITTS.

Brasie Corners, N. Y., Dec. 13, 1888.

OUR QUESTION-BOX.

With Replies from our best Authorities on Bees.

All queries sent in for this department should be briefly stated, and free from any possible ambiguity. The question or questions should be written upon a separate slip of paper, and marked, "For Our Question-Box."

QUESTION 97.—*a. In cellar wintering, do you think top ventilation necessary? b. If not, how much and in what way do you provide for bottom ventilation?*

I do.

MRS. L. HARRISON.

a. I do. b. I also leave open the whole width of the entrance.

GEO. GRIMM.

Some ventilation is necessary, and the difference in temperature is bound to cause a current.

DADANT & SON.

a. No. b. I leave the entrance of the hive open its entire width, $\frac{1}{2}$ inch in height. I should like better to have three times the space, however.

C. C. MILLER.

It does not make much difference about ventilation, and there is a wide difference in opinions regarding temperature; and all this comes about because the whole matter of safe wintering hinges on the food.

JAMES HEDDON.

A little top ventilation I think to be all right. A good deal might do no harm if a steady high temperature is kept in the cellar. As to its being exactly necessary in any case, I hardly think it is. b. Set the hive on blocks.

E. E. HASTY.

I think not, unless it be required to keep the temperature uniform, and at the proper point. If top ventilation of colony in hive is meant, I say no emphatically. I close at top entirely, but have entrance wide open. I would raise each colony 2 inches from bottom-board if I could easily.

A. J. COOK.

a. No. b. Ventilate at the bottom, only by placing the hives in rows with a space between each hive, then tier up, placing each hive over the space below. Set the first row of hives on covers arranged in the same way, or on stringers. This plan is fully described and illustrated in GLEANINGS, Feb. 1, 1888, p. 90.

H. R. BOARDMAN.

Upward ventilation is undesirable. I prefer a bottom-board with an opening in the center. I use an opening 5 x 10 inches. My methods all the year round require this. In winter quarters the bees cluster well down, and may usually be found in a cluster below the bottom of the frames. They are thus assured of their freedom; dead bees also drop out of the hive.

L. C. ROOT.

I don't know that I understand the question. If the ventilation of the cellar is meant, then I should say that it needs no special ventilation; if the questioner is speaking of the hives, then my plan would be to raise them off the bottom-board from two to twelve inches, leaving the top the same as in spring or fall when the sections are not on.

G. M. DOOLITTLE.

No, not usually; but with a warm cellar, with air near the point of saturation, a slow top ventilation may be necessary. We ventilate our hives by drawing a slide in the bottom-board. The slide is ten inches long, and is drawn open two or three inches, or even more, with the stronger swarms and warm cellars.

P. H. ELWOOD.

Not if the temperature is right. If the cellar is moist, the temperature should be higher than if the cellar is dry. I provide for bottom ventilation by removing the bottom-board and raising the hive one or two inches above what it sits on. To economize room I place a square stick an inch or more thick on top of each side of the hive, when in place, and set the next hive on these sticks, and so on as high as I can reach.

DR. A. B. MASON.

b. Dr. Jessie Oren, of Laporte City, Iowa, is as successful as any one I know of in cellar wintering, and his method of bottom ventilation of hives with tight bottom-boards is the best I know of. He sets his hives on ends, or, rather, on lower front corners, at an angle of about 45°, leaving entrances wide open. Succeeding hives are leaned against the first and others, and when the first tier is in place, wide boards are laid on top, then another tier of hives, etc. I inclose a rough diagram of the arrangement. This not only secures bottom ventilation, but allows dead bees and rubbish to drop from the hives during the winter.

O. O. POPPLETON.

OREN'S ARRANGEMENT OF HIVES *

The general opinion seems to be that top ventilation for the hive is not necessary, and that a full-width entrance, or else an open bottom, or nearly so, is sufficient. Dr. Oren's plan would doubtless work very nicely, and the bottom-board at all times would be clean of dead bees. Friends Elwood and Root accomplish the same result by leaving an opening through the bottom of the hive.

QUESTION 98.—*Is your cellar provided with a sub-earth ventilator? b. If so, has your experience taught you that they are an advantage, either for quieting bees or otherwise?*

a. No; b. No.

DADANT & SON.

a. It is; b. Yes.

MRS. L. HARRISON.

No. b. I have had no experience in line with this question.

E. E. HASTY.

a. Yes. b. I think so, but it is hard to be very positive.

C. C. MILLER.

No. I am quite certain that it is worse than useless.

H. R. BOARDMAN.

* The diagram above is not strictly correct. The adjacent corners should come in contact.

No. My ventilators consist of a chimney and several tin pipes.

GEO. GRIMM.

If other conditions be right, I think a ventilator at the bottom of the cellar not only unnecessary, but objectionable.

L. C. ROOT.

No. We use no sub-earth ventilators. We do not believe any good can come from them which will compensate for their cost.

JAMES HEDDON.

No. A chimney extends down into the cellar; and a stove set up for use, in case it is needed, will give all the upper and lower ventilation needed. I have never been annoyed with bees becoming uneasy in winter, unless they were short of stores or eating too much bee-bread.

DR. A. B. MASON.

Yes. For years I kept bees in such a cellar, with almost perfect success. Properly arranged it surely aids to keep the temperature uniform. Were I sure that I could accomplish this easily and cheaply, without such ventilation, then I would not arrange for it.

A. J. COOK.

Yes; but when I say it has been kept closed entirely for the past three years, it will be seen that I regard it of no value whatever. Were I to build another bee-cellar, I would make no provision for ventilation, as I believe enough air passes through the walls and ground to meet all of the requirements of the bees while in winter repose.

G. M. DOOLITTLE.

Yes. If properly put down they are beneficial. They keep a more uniform temperature. At one time, when the temperature outside was 17° below zero, the air as it entered the cellar was 37° above. Our sub-earth ventilator is made of glazed sewer pipe, one foot in diameter for the first hundred feet; for the second hundred feet, eight inches in diameter. At the end of the twelve-inch pipe is an opening, to be used in moderate weather; but in cold weather the whole length of the pipe is used. The joints of the pipe should be securely cemented to keep out the ground air, which is usually loaded with moisture, and heavily charged with carbonic-acid gas. The last is very variable, however. Were I to put down another ventilator I would use six-inch pipe, as being easier to make tight, and multiply them for capacity; also, if possible, I would have them extend in different directions, as the direction of the wind makes a difference in the draft of the pipe. I would also have one or more of them so laid as to act as drains in case of freshet. Ours is so put down, and last spring it was used to nearly its full capacity.

P. H. ELWOOD.

The answers to Question 98 seem to be a little bit perplexing; but Dr. Miller, Prof. Cook, and P. H. Elwood, all of whom have had large experience with sub-earth ventilators, declare quite emphatically in favor of them—especially friend Elwood. We hardly know how to account for the difference in testimony in regard to the value of these ventilators, unless it be because of the relative warmth and dryness of the various cellars, or because of the length or size of the ventilators. Dr. Miller has assured us that, several times when his bees seemed to grow uneasy, he could quiet them by opening the ventilator. We are quite loth to give up the idea just yet, that the sub-earth ventilators are not necessary or useful.

QUESTION 99.—a. *How many colonies, according to your best judgment, can be wintered with reasonable assurance of success in a dry cellar, 10x10x6, frost-proof, with no special means of ventilation other than is afforded by the usual cellar windows?* b. *How many cubic feet of space in a cellar do you regard as best suited for wintering 100 colonies, average strength?*

Forty.

H. R. BOARDMAN.

a. Just as many as you can put in.

DADANT & SON.

You could safely winter 100 colonies in such a cellar.

JAMES HEDDON.

I should say about 40. b. I should like at least 1200 cubic feet.

A. J. COOK.

a. 75 or 80. b. Not less than 1000; and in my judgment, 1200 or 1500 would be better.

MRS. L. HARRISON.

All other conditions being as they should be, 100 colonies can be wintered in a cellar of the size above mentioned.

L. C. ROOT.

I am a Yankee, and guess with native freedom; but it would be carrying matters too far to guess the answer to this.

E. E. HASTY.

a. I do not like the proportion of the dimensions you give; six feet high does not suit me. I would sooner have it 10x6x10. b. This question is hard to answer. I have wintered successfully 350 colonies in a cellar about 20x25x8.

GEO. GRIMM.

All you can get in, providing you leave at least six inches of open space under each hive. Still, I prefer an alleyway through the center of the cellar, so I can pass from one end to the other occasionally to see that all is right.

G. M. DOOLITTLE.

That will depend upon the temperature at which the cellar is kept, and the size of the hive they are kept in. Over 200 in Langstroth hives *might* be kept in such a cellar. I should not care for any special arrangements for ventilation in such a cellar, but should prefer to have not over 100 in a cellar of that size.

DR. A. B. MASON.

a. Two cellars may both answer the above description, and yet be very unlike as to temperature and openness of wall and soil. Perhaps 40. b. The more the better. Perhaps 1500 cubic feet; but best arrangements for admitting plenty of pure air at right temperature might make a good deal less answer. (Mind you, I don't warrant my answers to 99. They are taken at "purchaser's risk.")

C. C. MILLER.

a. This depends upon so many conditions that it is hard to answer. If there is a fire overhead, the air of the cellar will be changed quite rapidly, perhaps more rapidly than with some of the "special means" of ventilation. I should say, with the average conditions, from thirty to fifty. b. The answer to this also depends upon the cellar. Some cellars require pretty heavy stocking to keep the proper temperature. Properly arranged, a cellar of twice the above size would do.

P. H. ELWOOD.

A cellar 10x10x6 will hold from 40 to 100 colonies; and 1500 cubic feet seems to be about the capacity that is necessary in order to winter 100 colonies. This would make a cellar about 15x15x7. The answers to all these questions necessarily can not be exact; but surely our veterans can get very much nearer the truth than the average beginner, who proposes to winter bees in the cellar, can guess at it.

OUR HOMES.

NOTES OF TRAVEL.

Whosoever drinketh of the water that I shall give him shall never thirst; but the water that I shall give him shall be in him a well of water springing up into everlasting life.—JOHN 4: 14.

THE Ojai hot-springs (pronounced Ohi) are 15 miles from Ventura, in the Matilija canyon; the mountain scenery is some of the grandest I have seen.

Right opposite the hotel the mountain rises 1000 feet, almost perpendicular. Several objects of interest are found in the canyon, besides the springs. One of them,

THE DEVIL'S SLIDE, NEAR OJAI HOT SPRINGS, CAL.

called the Devil's Slide, we have reproduced from a photograph. It looks as if the boys, by riding down with their sleds, cut a path, or track, clear from the top of the mountain down the whole 1000 feet, to the river below. This appearance is caused by a stratum of rocks of regular and even thickness being turned up edgewise, with rock projecting a little higher on either side.

The picture was taken when the trees were in full leaf; but now the slide is visible clear down to the water.

To Huber.—Papa is in a strange country now. The sun has just gone down, and it is only 2 o'clock, just 2 hours after dinner time. The man who lives here says in a few days it won't get up above the awful big mountain at all for more than *six weeks*. Behind us is a fountain where the water spurts right straight up, higher than the house; and right down before us, around the great big clean white stones, is a spring where water just pours out that is *smoking hot*. Off up the creek a little way is another where the water is so hot you can hardly bear your hand in it. The men have made a long wooden box to carry the water to a little house where there are a lot of bath-tubs. I just took a bath, and it was real fun, I tell you, to have a big lot of real warm water pour right on to you. It is a funny kind of water, that doesn't need any soap—no, not even for papa's head, and I think even mamma herself would say my head is very clean now. I don't think I ever looked quite so white before in my life. Up in this canyon is a great place to keep bees, and the honey the bees get is the nicest in the world. I saw the man who first found out it was a good place for honey. One year he got more than a hundred wagon-loads of honey from his own apiary. The road he made to draw the bees up and get the honey out, you would think an awful road. It just shakes a body's breath out to ride over it. Sometimes he would stay up there in the mountain gorge, all alone, for two weeks, and not see anybody at all. One of the bee-men hired a boy to work for him. His name was Elmer. Well, he used to leave Elmer all alone there to work, and he didn't see anybody at all for days. One day when they came up, Elmer asked them if they couldn't bring him a cat or a dog, or something that had "the breath of life in it," to keep him company. They said one time he took the ax and chopped a great pile of wood, because he wanted something to do, and because he used to chop wood away back in his home, yet nobody wanted wood around here. Well, out here they have a great deal of trouble with bears. They come to the bee-hives and turn them over, and take their great paws and scoop out the bees and honey to eat. One time a bear spoiled so many hives that Mr. Shaw, the man who first went up here, stayed all night up in a tree, with his gun, to shoot him. He made a little house or cage up in the tree, so if the bear climbed up he could not get at him, and then they waited. About 11 o'clock, along came a great big grizzly bear, and commenced to paw the hives to pieces. The two men in the tree shot him until he was dead.

They have a great many California rats here; and where do you suppose they build their nests? Why, up in the tree-tops; and the way they do it is, that each rat takes a stick in his mouth and walks up the tree. I saw lots of their nests. These rats are very busy folks; they are always carrying something. A lady said the rats once got a habit of leaving a pile of sticks on her doorstep every morning; and to get rid of them, she used them to kindle the fire to get breakfast; and for a long time the rats gathered her kindlings every morning. Mr. Wilkin once lost his clock-key, and found the rats had carried it up garret and put it in an old stovepipe. They make their nests usually in walnut-trees, where it is handy to gather walnuts. Mr. Shaw says there is a place up near his apiary where the ground is so hot, winter and summer, that you can hardly stand on it.

GENERAL NOTES.

I supposed, of course, the heat from these hot-springs was caused by volcanic agency; but the proprietor says it is supposed to be caused by chemical action. These mountains are full of minerals; and when the water from the rains passes over a certain chemical it becomes impregnated, and then dissolves another of just the right kind. Thus great heat is given out. Sulphuric acid and water, when mixed in the right proportions, will become boiling hot. I think one of the prominent chemicals in this water is a salt of iron. I can not see, however, how this should produce that hot spot in the ground, which Mr. Shaw spoke of.

Castor beans here form trees; and even the beautiful fuschia is a hard-wood tree. Imagine a tree covered with fuschia blossoms, more beautiful, larger, and more perfect, than those in greenhouses at home. The century-plant also blooms here. In passing a garden I asked what kind of a tree it was that loomed above all the rest.

"Why, that is the flower-stalk of the century-plant," was the reply. ☐

"But it isn't possible," said I, "that this great tree all grew in one season?"

"Mr. Root, that *great tree* all grew in *just a few weeks*," was the answer. After it blooms, the plant dies. The one I saw was said to be about 30 years old. The plant had been all these years accumulating material for this grand finale—the sending-up of the blossom and seed-stalk. I am impressed with the thought that we are something like the century-plant. We are, during this life, accumulating knowledge, and strength of character, for some grand finale in the great future; but while the century-plant dies down after it, *we are to have* "life eternal."

Dec. 1. Through the kindness of friend Wilkin and Mr. and Mrs. Mercer, I have again had a most pleasant drive through the country to Santa Paula. While there we had a sort of bee-keeper's picnic. I was greatly pleased to meet no less a personage than J. G. Cory, the inventor of the Cory cold-blast smoker, who was a resident of the place. Our older readers will remember the story of friend Cory's kind present. Rufus Touchton, who has written some for

GLEANINGS, is also a resident of Santa Paula. The great center of the oil regions of Ventura Co. is here. A single one of the storing-tanks is 100 feet in diameter, and 25 feet high. From the pipes coming in from different wells, *2000 barrels of oil daily* is emptied into this immense tank. While we were there, by an accident to one of the pipes the oil flowed over the ground so that the men had to turn out with shovels and dam it up until it could be secured. There is quite an extensive oil refinery here. The boilers for working their immense pumps are run with oil as fuel. Between Ventura and Santa Paula are immense farms for corn and barley, and excellent corn was seen all along the way, piled up in immense heaps in the field. Corn-shellers, run by steam, shell and bag it. Plowing is mostly done by a gang of three or four plows drawn by four or six horses. The valley is one of the finest for fruit and grain, that will succeed without irrigation, of any that I have seen. Apricot and English-walnut orchards occupy mile after mile of the land. Great evaporating-houses for the fruit are seen at intervals all along. Immense corn-crisps, without any roofs, are also found, but I believe the best farmers cover their corn in the winter time. Cattle and horses seldom have any roofs over them on the farms. They say, when they have sheds, the animals never go under them, even in *winter*, when it rains. It usually rains in the night time, and sunshine is the rule every *day* in the year. It has rained nearly all of one day since I have been here, but I am told the like has not happened before, since three years ago. Winter and summer are very much alike, only the days are shorter in winter. It seems odd to have this beautiful spring weather, and yet see the days so short. The sun rises now about 7 and sets about 4.

Dec. 2.—Another glorious Sabbath day. I got acquainted with the pastor of the Ventura Congregational church on Saturday; but as he was prevented by sudden illness from preaching, it was suggested, as it was late to go to other churches, that we have a prayer and devotional meeting, instead of the regular services, and very soon it was suggested a stranger from Ohio was present, who was quite a Christian worker, and the leader called upon "Bro. Root" to tell us something of Christian work in Ohio. At the close a number gathered around me as before, and I tell you it made me feel happy to hear different ones say they knew me because they had read my writings. I felt happy to remember that almost every thing I have ever written, told, sooner or later, for Christ Jesus. At the opening of the Sunday-school I was assigned the Bible-class; and learning there was a mission school two miles away that the pastor usually took charge of, by the kindness of friend Mercer we were on hand at half-past two. The key to the schoolhouse was lost, however, and the crowd gathered there had to postpone the school and go home. We got back to town just in time to attend a meeting of the Y. M. C. A., and a most able talk was given us by one of the merchants. The attend-

ance was good, and almost all took part. After this we attended the Endeavor Society, and the leader very soon called on "Bro. Root." The attendance here was nearly all young ladies. The leader told me they were sorry that they had so far been unable to get many of the young men interested. They sent very kind messages to the Society in Medina. They take the *Golden Rule*, and think much of it. The leader mentioned in my talk with her that she had but little time to spare, as three of them had in charge a Chinese Sunday-school, and the pupils were probably waiting for them then. I begged to go along, and, on account of a vacancy, I was called upon to explain the lesson to a lot of Chinese brothers. Yes, *brothers* they are, no matter how they came here, or what the purpose. They answered questions quite freely; and when the teacher told them to let the stranger see how well they could write on the blackboard, they expressed their gratitude to me by well-worded and neatly written sentences in our language. Then they wrote for me in Chinese. At the close of the school they repeated the Lord's prayer, first in English and then in Chinese; and after the school was over, one of them gave me some of their tea from a beautiful China teapot, kept warm in a padded flannel cushioned basket. The Chinese here are very neatly and cleanly dressed, and the boys in the school were, most of them, intelligent, fine-looking fellows. I questioned them pretty closely in my talk with them in the class, and the teacher tells me they told the truth when they said they did not drink, swear, nor steal. She also says Chinamen always pay their debts, and seldom waste time in idleness. As I talked with them I thought of Bro. Ament* and his labors; and when I walked home, pretty well tired with the labors of the day, you need not be surprised when I tell you I had one of those bright experiences that seem to give a glimpse of the heaven that awaits those who delight in being servants of the Lord. Why, the delight in meeting with such beautiful and grand Christian characters as I have met to-day, both among the men and women, is enough to make one break forth in praises to God; and it is not to-day only, but every Sunday since I have left home; and the probability is, that I should be able to find more like them in every town and city, were I to travel *months* and *years*, for I have had the peace of God in my *own heart*, and this has helped me to find Christian people, and to appreciate their good qualities when found. Does some one suggest that, if I were to live by these people day after day, I would think differently of them? God forbid! The person who has in himself the "living water," "springing up into everlasting life," will always find good neighbors, no matter where he is. Dear reader, what kind of neighbors are round about *you*?

Dec. 3.—*To Huber.* Where papa is now,

*The pastor of our church. He has been with us for about four years. The most of his life previous to that time was spent in China. His people, however, kept sending so continually for him to come back that he left us a few months ago to resume his labors at his old home.

the men who ride on horses carry long leather ropes, called lassoes, that they can throw so true as to catch a cow or a horse that is running away, or even catch a man if they want to. These horses with lassoes attached to their saddles are almost always standing hitched in the town; and whenever a team runs away, one of the Spaniards is sure to lasso the horses and stop them before they have gone very far. They have a slip noose in the end of the long leather rope, that they throw over the head or catch the heels of the cow or horse. Some time ago a couple of Spaniards were riding along, and a great grizzly bear came at them. As quick as a wink one horseman threw his lasso over the bear's head, and tried to choke him; but the bear chased the man and horse until the other man lassoed one of his hind legs. Then they had Mr. Bear in a fix. When he tried to get *one* man, the other held him off; and if he tried to get the other, *he* held him off. In this way they tired him out, and really brought him into town, to the great delight of all the town people, especially the *small boys*. The horses the Spaniards ride are trained so that, when their rider throws a lasso, they brace themselves and pull with all their might to hold a cow or horse; in fact, they say they rather like the fun. They tell you here that, if a bear chases you, you must not try to get away by running down hill or up hill, but just run along the side-hill; and as the bear's legs are not made for side-hill running, he will tumble down and roll over every once in a while; and this takes so much time that the man can get away from him.

Dec. 3, just before going to bed. Here I am, away up in a little notch amid the mountains. Of all the winding, tortuous roads, I never before traversed one like this. I am staying with Mr. Thomas Arundel, or better known by the bee-men as "Tommy Irondale." Bee-keepers have been pushed back by the fruit-men until many of them have gone way back, where the bees can't intrude or hinder, and in this way friend A. has found his pleasant home. When he found his bees here in this wild glen gave more and better honey than any of the rest, he persuaded a charming girl, with energy and determination like his own, to share his lot; and here, three miles or more from any neighbors, they have reared their children, four in number. The oldest is now about 7. It seemed odd indeed to find so pleasant a home after three miles of crooks and turns, without seeing a house; and when my neat little room was assigned me, with its many little evidences of feminine taste, so cosy and snug and pretty, I could hardly feel as if I deserved it. I felt like saying, "A. I. Root, what have *you* done to entitle you to the best of every thing everywhere you go? Why should these good people labor and toil to fix up nice pleasant homes, and then place them at your disposal?" To tell the truth, I do feel every day as if I deserved no such kindness; but every little while I get a hint of *why* I am thus honored. As we turned the last curve, and came out through the leafy trees in sight of the col-

tage, friend A. spoke of what I had written in regard to finding that spring of water, of my talk about hydraulic rams, and the wind-mill, and of a pet project of his own to bring that babbling brook to his house, just above us; and then I saw that GLEANINGS had been read*, and my investigations had been eagerly followed by many I did not then know, and in homes I at the time had no knowledge of. Later, when I heard how the good mother had taken these little ones to Sunday-school at the schoolhouse, three miles away, even when a California lion glared at them through the bushes on their way home, I remembered too of the times when I, in my poor way, had tried to tell of the "living water," springing up into everlasting life, and that, in all probability, the dear ones in this home too had been interested, and may be had been helped in that way. Prominently on the neat little stand on which I write is a little Bible, evidently placed there by the same hand that fixed the rest of the room so trim and neat, feeling sure that Mr. Root would want it. May God be praised for this act. I do want it; I want it while I live, and I want it when I die. I want it always near me. Dear reader, I haven't room to tell you of all these homes; but this one is a sample of most of them, and I hope I may never forget to pray for the dear brothers and sisters I have found here in California.

During the day I visited the Sespe Apiary, illustrated in the A B C book. Friend Wilkin now no longer owns it, but it has been turned over to a bright muscular young Canadian, who not only gives it excellent care, but cares for friend W.'s youngest daughter also, and the two handsome children God has given them. Young McIntyre has the best-kept apiary and honey-house I have so far found in California. He brings in the combs to extract on a two-wheeled cart. The cart contains two boxes for holding the combs, with cloth covers to keep out robbers. The cloth is fastened to the box at one edge, and a stick is fastened to the other edge, heavy enough to keep the wind from blowing it away. I will describe his can for holding the cappings at some future time, with suitable engravings. As I passed through Santa Paula, Rufus Touchton handed me a box of beautiful large strawberries. All the bee-friends seem to know of my interest in strawberries, and I was a good deal "touched" by the compliment and courtesy.

AN OPTICAL ILLUSION.

When you are driving on a level road that runs straight toward a range of mountains, when about a mile away from the mountains you will feel sure you are going down hill. Even when going up hill toward the mountains I was so sure it was down that I became almost tired with my friends when they declared it was not down. In fact, I could not believe it until we came to a stream of water, and I was then startled to

find it running up hill! If you turn about, however, and look behind you, every thing looks right. Old residents learn to allow for this deception; but new comers are very much astonished.

December 4.—To Huber. O Huber! I wish you could be with papa just a few minutes. All around me are the great mountains, with the sun shining on their peaks. Before me is a beautiful green tree, just splendid with loads of red berries. Beside me are Frankie and his sister, and Norman is drawing his wagon up the hill, and Louisa is the baby. The boys are bareheaded and barefooted right here in the winter. They are asking me why I did not bring Huber along. I have just been up the canyon a mile or more to see a beautiful waterfall. The water comes down from about as high as the chimney to our house; and the funny part of it is, that the water itself has made a trough on the back side of the falls, so it just slides down. The water is of a kind that covers every thing with stone. I had to climb like every thing to get up to the fall; but as the buggy was waiting for me, I skipped back down the rocks pretty lively. I feel real strong and well and happy. The buggy is waiting now, so I must stop writing and bid the little prattlers and their mamma good-by. Off we go among the great mountains again, and find another bee-man. There are lots of bears around here, and they trouble the bee-keepers. I have just been looking at a big oak-tree that has great scars on its bark, made by a bear's claws. Mr. Reasoner had bad luck with his bees one year, so that only 11 colonies were left. Well, an old bear came every night and clawed the honey out until only one of the 11 was left, and Mr. R. wanted so bad to keep that one that he hung it up in the tree by a rope, so high the old bear could not reach it. He could not carry it away, for the bees that were gathering honey would be lost; but if it were hung up they could find it. Well, that night the bear came after more honey; and as he could not reach that last hive, he clawed up the tree and commenced to slide down on the rope, to get the bees. Now, the rope held the hive very well, but it wouldn't hold a big bear too, and so it broke, and down came bear, bees, and all. I guess he must have been somewhat astonished; but he gathered himself up and ate all the honey, and then went off. As he had now got the last one, Mr. R. thought he wouldn't come any more; but back he came the next night. Well, the bees that had no hives wanted to work somewhere, and so they went into the bee-house near by, and built some combs under the clock-shelf, and, don't you believe that that old bear smelled the honey under the clock-shelf and wanted that too? but as the honey-house was shut up and locked, he could not get in; but he made a hole in one corner with his teeth and claws until he could get one paw through, and then he reached in as far as he could and tried to claw down that last bit of honey the poor bees had made. I saw the place where he made the hole in the bee-house.

And now it is night again, and papa is

* The most prominent thing in friend Arundel's library is volumes of GLEANINGS, neatly bound, and lettered on the back in home-made binding and lettering.

away off alone in the wilderness waiting for a train. The train never stops here unless some one burns a newspaper and waves it across the track to let them see that somebody wants to get on. As it is awful dark, and papa has got to wait over an hour, he has built a fire of sticks, and the kiotes have come up as near the fire as they dare, and are making an awful barking and growling. Papa is almost afraid some bad men might see the fire, and come to rob him. Pretty soon he hears somebody. It is a man who has been up in the mountains digging gold, and he shows papa by the light of the fire the gold he dug to-day. Pretty soon another awful big man comes up, swearing fearfully, because he says nobody will give him work, and he hasn't any money. Papa is awful glad the other man is there, and he gives the bad man a real good talking-to, because he swears so bad. Then the bad man pulls out a bottle of whisky and wants us to drink; but when he finds we are both temperance men he goes off in the dark, swearing harder, and saying he never saw two such men before in his life, that won't drink when somebody offers to give it to them! Just here the old locomotive came in sight; the gold miner waved the burning paper, and we were soon in the cars among nice people. In just a few minutes more we stopped at a nice town where supper was all ready, and a man was pounding a gong to get us to come in and eat it. Now just think how funny! This gold miner knows Uncle Hen's cousin, and he is going to help me to find him. He also asked me to go with him out in the mountains and see him dig gold, but I don't think I shall have time.

Dec. 5.—There are now but few small beekeepers in California—at least I have not found them. I have visited nearly a dozen apiaries, and few of them are less than 300. Most of them admit that a smaller number would do better in one locality, but the convenience of having all in one place overbalances. Most of them live in the towns, and have their bees located in the mountains, and look after them only occasionally, except during the honey-flow. McIntyre, Arundel, the Reasoner Bros., our old friend Lechler (who gave us that wonderful report some years ago), Marple, and Sniffin, all live near their bees. I am greatly indebted to the first three for leaving their work and passing me from one to the other, over and through the mountains, and up the canyons. A good many, I find, are discarding the hexagonal apiary, or, rather, modifying it so as to have the hives stand in double rows, radiating from a common center like the spokes of a wheel. The alley formed between the double rows is for running a cart or wheelbarrow through, for carrying the honey to the honey-house, the entrances to the hives being all turned outward, so that the operator and cart never stand in the way of the flight of the bees. Friend Reasoner has grapevines also, planted near the hives for shade, with this form of apiary. His hives are all neatly painted. Friend Lechler has his in long rows under live-oak trees, and says he always gets most honey

from hives in densest shade. This is an important item. Another thing in favor of shade-trees is, that they take the strength (or moisture) from the ground so thoroughly that no weeds grow, and the ground under the trees is as clean as a floor. Almost all agree that, where many hives are all alike, the bees are constantly going into the hives on the *outside* of the apiary. I think this should be corrected by having the hives made more unlike in some way.

Friend Reasoner helped me to ascend the first big mountain. I say helped, for I could not well have done it alone. I wanted to see the end, or termination, of a canyon, so we took a light cart, or sulky, and a big strong horse. When the horse began to get tired he walked while I drove along on the winding slope, all the time on the edge of a frightful abyss. When the horse got tired with me alone, I too went afoot until we came to the dividing ridge. Here the canyon ends; but right over the edge of the sharp ridge another canyon begins, taking the water in an opposite direction, and thus it is there are no mountains without their accompanying water-courses.

Well, my friend said he would stay with the horse on the ridge, while I walked along it until I came to a higher elevation, a real mountain peak. Strange to tell, the ground on these mountain peaks is soft and yielding, and mellow enough for a beautiful garden. As I went up, up, the sides became steeper; and as I gazed into the frightful abyss all around I became dizzy; then my throat began to be dry and to smart, and finally my ears began to feel strangely on account of the rarity of the air. Once I began to think of going back, as my breath got so short; then I discovered a faint path across the side-hill at an angle, and this I found much easier. Spanish bayonets were all around me, and their leaves were so sharp they went right through my clothing, so I had to pick my way. The summit is finally reached, and from the dizzy height I see only other summits like my own, in every direction except toward the ocean. I could not see its waters, but there seemed a sort of vacancy in that direction. All around was one vast solitary ruin of nature. My friend and his horse looked like rats, and yet they were up miles from the valley below. I was surprised to find these mountain peaks quite well frequented by different kinds of wild animals, as was evident by their excrement, which was so plentiful and some of it of such large size I guessed it must have been from bears and mountain lions, as well as wildcats and smaller animals. I do not know what should call them to these extreme peaks. I judged they were mostly flesh-eating animals. Mountains are wonderfully deceptive to the uninitiated. Mr. McIntyre told me a peak before the house was two miles away, when it was apparently right close by. I could not realize it until he pointed out some animals near its summit, and asked me what they were. They were little specks that I thought might be small pigs until he told me they were cows. Again, we often came to the "end of the road," apparently. The mountain was sure-

ly entire, and without any crevice or opening; yet as we went on, before you knew how it came about, a canyon opened, where, a few minutes before, was the clear smooth mountain-side.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, OHIO.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, JAN. 1, 1889.

Before the mountains were brought forth, or ever thou hadst formed the earth and the world, even from everlasting to everlasting, thou art God. PSALM 90: 2.

RENEWALS are coming in rapidly and promptly, for which we tender thanks. We have 842 names.

MANY kind expressions come in in regard to the biographical sketches. See Kind Words elsewhere.

MY VISIT TO CALIFORNIA.

THESE notes of travel will occupy considerable space in several issues yet—probably until March 1.

A WEDDING-CARD.

THE following announcement, gotten up in the latest style of the art, comes to hand:

Married, Thursday, December twenty-seventh, 1888, Husted, N. Y., Julia C. Collin, Geo. H. Knickerbocker.

We extend our hearty congratulations.

LOSS BY FIRE.

WE are advised that the first installment of the Langstroth Revised was destroyed by fire while in the book-bindery. As a consequence, the work will not appear as soon as it was anticipated. The loss was covered by insurance, and the delay will be of comparatively short duration.

DEVICES FOR CARRYING HIVES.

WE have received a host of letters on the subject as above—more than we expected. We extend our thanks to one and all. The most of the devices for the purpose are quite similar in principle. We hope to illustrate one or two of the best soon; but for the present it will hardly be worth your while to send in more suggestions.

AT HOME AGAIN.

I AM once more (Dec. 20) at home again. The past few weeks seem so much like a dream that every little while I have to shake myself and look around to make sure that I am in wintry Medina instead of away off in California, the land of perpetual flowers and sunshine. I am glad I am here, though, after all.

THE IGNOTUM TOMATO.

EVER so many have been asking whether the seed of this tomato is all gone yet. To be sure, it is not. We had about 5000 packages prepared to give away to our readers, and I do not think we have given away 1000 so far. Every subscriber of GLEANINGS who raises tomatoes may have a sample

package, simply by asking for it when they renew, or telling us on a postal card at any other time.

GARDEN-SEEDS FOR 1889.

NOT only in Florida, but in California and other points in the West and Southwest, we are having quite a little call for garden-seeds, and we accordingly submit a list with prices in this issue. I am experimenting with and testing pretty much all of the novelties, but I have not found any of them sufficiently satisfactory to warrant me in giving them a place in our list, except those already mentioned. I would say, however, that some of the new things will be recommended if they behave as well another season as they have during the past.

ACCEPTABLE MATTER FOR GLEANINGS.

THERE is a big pile of copy on our desk, awaiting insertion. It can't all find a place, and, according to the rule of the survival of the fittest, some of it we fear will have to go unprinted. At times we have so much copy that even good and valuable matter shares a similar fate. Remember, our space for articles, especially long ones, is limited; but we will make room for short pithy items. Questions are always acceptable when briefly stated, and when written upon a separate slip of paper. Don't expect an answer—at least, not immediately, if you mix your questions up with other matter.

PROFESSIONAL MEN IN OUR RANKS.

CONCERNING the biographical sketches and the portraits in the A B C form in last issue, one of our correspondents, G. C. Hughes, Pipestem, W. Va., well says: "After a glance at the intelligent faces, one would suppose that the members of the bee-fraternity are second to none—not even those of the legal profession." Very true, and yet it is not surprising; for there are lawyers, doctors (lots of 'em), professors, ministers, and, and—even editors (beg pardon) in our ranks. Of the non-professional men with us, we need not be ashamed. We have great reason to be proud of our representative bee-keepers. They would and do adorn and honor almost any calling.

ERRATUM.

ON page 961, Dec. 15, just below the diagram, instead of the expression, "Now, the mountains in the table lands," it should read, "Now, the mountains composing our great mountain ranges," etc. The idea is, where we find mountains composed of regular level strata, it indicates that the surrounding land and rocks have been washed or worn away; whereas the real mountains proper have their strata tipped obliquely, and sometimes clear up to the perpendicular, indicating that they have been thrown up by earthquakes or volcanic action. In Arizona and New Mexico the mountains like the diagram are quite common; but in California, along the Rocky Mountains, and through Utah and Colorado, they are of the other sort—see p. 27. Of course, the action of the wind and water is constantly wearing down and modifying both kinds.

POTATOES—DOES THE VARIETY HAVE ANY INFLUENCE ON THEIR ROTTING?

I HAVE always been a little skeptical in regard to this matter until the past season. On our creek-bottom ground we raised tremendous crops of Early Ohio, Early Pearl, Lee's Favorite, and Empire State, with scarcely a rotten potato in several

hundred bushels. Well, right on the same ground we planted one row of a choice variety of potatoes sent us to be tested. When the hands were digging the others I thought I would dig this new variety. Now, although there was a very good show of tops when they were green, imagine my surprise to find not a potato of any kind or size in the first hill. When the second hill turned out the same way, I called the boys to know what the matter was. The reply was, "They all rotted quite a spell ago;" and on looking closely I found the remains of what had been potatoes. I did not find a potato fit to cook, for a sample, in the whole row. It seems to me that this settles the matter, that some varieties of potatoes are much more disposed to rot than others, and I shall have to tell my friend that his new seedling is not a success in our locality. As our potatoes were on rather low ground, and we have had an unusual amount of rain this season, during a dry season the result may not be the same.

CALIFORNIA CLIMATE FOR HEALTH.

I NEVER in my life weighed more than about 130 pounds, without my overcoat; but on my return from California I pulled down 142 strong. I occasionally take my before-dinner nap; but I am feeling so well most of the time that it is hard for me to sleep. And those spells of nervous prostration, which I have mentioned, have disappeared almost entirely, even if I work steadily in the office all the forenoon. Very likely, however, rambling over the mountains in the open air, and being outdoors almost all the time, would have almost as beneficial an effect in our climate as it would have in California. There is this about Southern California, however: Their climate is such, even in the winter time, that most people prefer to be outdoors the greater part of the time; and even while indoors, the doors and windows are open so much there is but little danger from suffering from stagnated atmosphere. Another thing: The greater part of the buildings have more or less openings that admit pure air, even if one should forget to open the doors and windows. I heard a good many object to having houses lathed and plastered, because the lath and plaster cut off the circulation of the air, more or less. Our stenographer adds, by way of a joke, "Climate is good, but 'climbit' is better."

SPECIAL NOTICES.

A BIG BARGAIN IN LETTER, NOTE, AND STATEMENT HEADS; ALSO LABELS OF GLAZED PAPERS.

A paper firm near us has recently become insolvent, in consequence of which we have secured some very fine label stock, also letter and note paper, statements and bill-heads. Any of our readers who are in need of any thing in this line will do well to write for samples and prices.

CHEESE-CLOTH AND COTTON SHEETING AT A BARGAIN.

We use both the above fabrics in making strainers and covers for our honey-extractors. In making an order recently, we, by a misuse of terms, got more than we intended. We accordingly offer it to our readers as follows: Cheese-cloth, 5 cts. per yard; 10 yards, 45 cts. By the piece of 60 yards, 3½ cts. per yard. This is 36 inches wide. Cotton sheeting, 36 inches wide, weighing 11 lbs. to the piece of 40 yards, 8 cts. per yard; 10 yards, 75 cts.

By the piece of 40 yards, 7 cts. per yard. If you would like to see what you are getting before you order, we can mail you a small sample on application.

THE CHICAGO SINGER SEWING-MACHINE.

Our readers will remember that, in our premium list issued with the Nov. 15th number of GLEANINGS, we devoted a full page to the above machine, offering them as premiums, also for cash. Several of our readers somehow got the impression that it was an advertisement inserted by us for the manufacturers of the machine, and have been writing them direct, only to have their letters forwarded to us for reply. We wish to say that the company do not sell the machines retail, but only through newspapers and journals. If you wish to know anything further than we have said in regard to them in premium list, please write to us, not to the company in Chicago.

REDUCTION IN THE PRICE OF BOXWOOD POCKET-RULES.

We have just laid in a new supply of pocket-rules, and can offer you better value for the money than ever before. The following is our complete list, with prices:

Post.	Name and description.	Price.	10	100
2	RULE, 1-FOOT, FOUR FOLD, round joint, No. 69	10	45	40

This is the very same rule we have been selling for years at 10 cts. each. We have now got them down to the five-cent counter.

2	RULE, 1-FOOT, FOUR FOLD, SQUARE JOINT, EDGE PLATES, No. 64	10	84	80
---	--	----	----	----

This has much stronger joints than the five-cent one; other wise it is no different.

3	RULE, 2-FOOT, FOUR FOLD, SQUARE JOINT, No. 61	10	84	80
---	---	----	----	----

An excellent rule for the money; has better joints than our old 10-cent one.

4	RULE, 2-FOOT, FOUR FOLD, HALF BOUND, No. 84	25	10	20
---	---	----	----	----

This is the very rule we have sold for years at 35c. It is brass bound on the outside edges.

5	RULE, 2-FOOT, FOUR FOLD, No 60, double-arch joint, full brass bound	35	10	30
---	---	----	----	----

This is our new 35-cent rule; is much better than the old, and I don't believe you will find it sold anywhere else for less than 50 cents.

6	RULE, 2-FOOT, 4 FOLD, 1½ in., No. 78½	50	40	40
---	---------------------------------------	----	----	----

This is the best rule of its size made. It is just like the 35-cent one, except it is 1½ wide, closed, while the 35-cent one is 1 inch.

3	RULE, 2-FOOT, 6 FOLD, No. 58. Arch joint and edge plates	35	30	28
---	--	----	----	----

Closes to 4 inches in length, which is sometimes convenient.

3	RULE, 1-FOOT, CALIPER, No. 32, arch joint, four fold	25	10	20
---	--	----	----	----

We formerly sold this rule for 50 cts.; but for a year or two at 35; now we have it down to 25.

4	RULE, 1-FOOT, CALIPER, No. 32½, arch joint, brass bound, four fold	35	10	30
---	--	----	----	----

This is the same as the 25-cent one, but is brass bound, and the best rule of its size made.

4	RULE, 1-FOOT, CALIPER, TWO FOLD, No. 36½	25	10	20
---	--	----	----	----

This is a very convenient rule sometimes, as it will caliper 5 inches.

2	RULE, 6-INCH, CALIPER, TWO FOLD, No. 36	15	10	13
---	---	----	----	----

We sold this for years at 25 cents; afterward at 20; now it is down to 15 cents.

All the above rules are made of boxwood, by the Stanley Rule and Level Co., who have the highest reputation for this class of goods of any manufacturers we know of.

SEEDS

Our sales in 1888 double those of 1887. Why? Because we sell only the Best, at Reasonable Prices.

Small Fruit Plants and Trees, Catalogue Free.

FRANK FORD & SONS, Ravenna, Ohio.

WANTED.—To exchange 250 colonies of bees, for horses, mules, wagons, buggies, and 4 h. p. engine, or any thing useful on a plantation.

THE "REVIEW."

THE BEE KEEPERS' REVIEW for Dec. has four extra pages—twenty in all. Upon the first page is a brief history of the "REVIEW," also an excellent

PORTRAIT OF ITS EDITOR

—one of those beautiful lives reproductions. The special topic of this issue is: "Sections and their Adjustment on the Hives," and it is handled by such men as Jas. Heddon, Dr. C. C. Miller, R. L. Taylor, Oliver Foster, and Dr. G. L. Tinker. A copy of this issue will be cheerfully sent free to all who apply. Price of the "REVIEW" 50 cts. a year.

The Production of Comb Honey.

Although this neat little book contains only 45 pages, it furnishes as much practical, valuable information as is often found in a book of twice its size. It is "boiled down."

It begins with taking the bees from the cellar and goes over the ground briefly, clearly and concisely, until the honey is off the hives; touching upon the most important points; and especially does it teach when, where and how foundation can be used to the best advantage; when combs are preferable, and when it is more profitable to allow the bees to build their own combs. Price of the book, 25 cts.

SPECIAL OFFERS.

For 65 cts. we will send the REVIEW one year and "The Production of Comb Honey." For \$1.00 we will send all the numbers of the REVIEW for the past year (1888), the REVIEW for this year (1889) and the "Production of Comb Honey;" or, for the same amount (\$1.00), we will send the REVIEW for two years from Jan. 1st, 1889, and "The Production of Comb Honey." Stamps taken, either U. S. or Canadian. Address 1ftdb

Cash for Beeswax!

Will pay 20c per lb. cash, or 23c in trade for any quantity of good, fair, average beeswax, delivered at our R. R. station. The same will be sold to those who wish to purchase, at 27c per lb., or 30c for best selected wax.

Unless you put your name on the box, and notify us by mail of amount sent, I can not hold myself responsible for mistakes. It will not pay as a general thing to send wax by express.

A. I. ROOT, Medina, Ohio.

HONEY COLUMN.

CITY MARKETS.

CHICAGO.—*Honey.*—The new year opens up with a quiet trade generally. Honey sells in a single-case way. Prices are lower than in November on all grades, excepting, perhaps, choice white comb in small sections and cartons. This is not plentiful, and brings 17@18c. But there is so much graded "white" by the producer that does not meet the views of purchasers as to cause more or less dissatisfaction; and such prices as can be obtained are accepted for the "off" grades. Extracted remains about the same; demand light. *Beeswax*, 22.
Jan. 7.

R. A. BURNETT,
161 South Water St., Chicago, Ill.

NEW YORK.—*Honey.*—We are forced to report a dull market. Stocks are light, but demand very limited, which we presume is due to the mild and unseasonable weather. We quote: Fancy white, 1-lb. sections, 14@15c; 2-lb., 12c; fair white, 1-lb., 12@13; 2-lb., 10@11c; buckwheat, 1-lb., 10@11; 2-lb., 9@10c; extracted, white, 7½@8; buckwheat, do., 6@6½. The latter is in fair demand, and we would advise bee-keepers who have any on hand to ship here.
Jan. 10.

HILDRETH BROS. & SEGLKEN,
28 & 30 West Broadway, New York.

KANSAS CITY.—*Honey.*—Choice 1-lb. sections, 15@16; dark 1-lb., 12; 2-lb., 14; dark, 11. White extracted in 60-lb. cans, 8; amber, 7; in barrels and kegs, 5@8. Demand good, prices steady, and stock large. *Beeswax.*—None in market.
Jan. 4.

HAMBLIN & BEARSS,
514 Walnut St., Kansas City, Mo.

CINCINNATI.—*Honey.* There is no change in the market. Demand slow, with a smaller supply than ever before at this season for the last 10 years. Extracted honey brings 5@8 on arrival. Comb honey, 12@16, in the jobbing way.

Beeswax.—Demand is good; it brings 20@22 for good to choice yellow on arrival.

Jan. 9. CHAS. F. MUTH & SON,
Cincinnati, Ohio.

KANSAS CITY.—*Honey.*—Honey is moving more freely. We quote white 1-lb. comb, 16@17; fall, 1-lb. comb, 14@15. California, 1-lb. comb, 16@17; same, 2-lb., 12@15. Extracted, 7@8. *Beeswax*, 20.
Jan. 7.

CLEMONS, CLOON & CO.,
Kansas City, Mo.

ALBANY.—*Honey.*—Market very slow, as usual after holidays. May do better a month later, but will depend on how much stock is left over.
Jan. 8.

H. R. WRIGHT,
Albany, N. Y.

ST. LOUIS.—*Honey.*—Our market is well supplied with California in cans. Local shipments scarce; demand fair. We quote, barrels, 5½@6½. Cans, 7@7½. Comb, 14@16. *Beeswax*, 20.
Jan. 7.

D. G. TUTT GROCER CO.,
St. Louis, Mo.

COLUMBUS.—*Honey.*—No change in our market. Sales very slow. No. 1 white clover, in 1-lb. sections, 17@18. Dark, 15@16.
Jan. 9.

EARLE CLICKENGER,
Columbus, Ohio.

DETROIT.—*Honey.*—White comb, in one-pound sections, quoted at 16@18c; sales slow, but the supply is gradually decreasing. Extracted dull at 7@8. *Beeswax*, 22@23.
Jan. 7.

M. H. HUNT,
Bell Branch, Mich.

No change in honey. BLAKE & RIPLEY,
Jan. 7. Boston, Mass.

FOR SALE.—A few cases of choice white comb honey in sections at 16c per lb., delivered at express or freight office here. Cases weigh 22 to 27 lbs.
A. FIDDES, Centralia, Marion Co., Ill.

FOR SALE.—800 lbs. or more of a good quality of white honey, in crates holding 12 sections, weighing about 11 lbs. to the crate. I will take 14 cts. per lb., f. o. b. here.

JOHN HANDEL,
Savanna, Carroll Co., Ill.

SPECIAL NOTICES.

PRICE OF CLOVER SEED ADVANCED.

Both alsike and peavine clovers have advanced in price recently, so that we can not furnish seed at the prices named in our catalogue. Prices for the present will be as follows: Alsike, 20 cts. per lb.; \$2.25 per peck; \$4.40 per ¼-bushel; \$8.50 per bushel. Peavine, or mammoth clover, 15 cts. per lb.; \$1.80 per peck; \$3.50 per ¼-bushel; \$6.50 per bushel.

JAPANESE BUCKWHEAT.

Any one who is not satisfied by this time of the great superiority of this new grain over the common, or, in fact, all other kinds, has only to read the reports in our agricultural journals. We have at present on hand, ready for the season's trade, between 300 and 400 bushels; and, judging from the prices at which it is offered in the various seed catalogues, compared with the prices we give, it would be nothing strange if every pound should be gone before time for sowing, and very likely we shall be compelled to advance prices as we have done for each season since it came out; therefore it behooves you to get your orders in early. Get your seed by freight, so as to save express charges, and then when you get your ground ready you will not have to telegraph for seed by express, and perhaps then be told that it is sold, and no more can be had. Compare the prices you find in the various seed catalogues with our own, which are: Bushel, \$2.00; half bushel, \$1.25; peck, 75 cts.; pound, 10 cts. By mail, add 9 cts. extra for each pound. Remember, our prices also include bags.

A WATERBURY WATCH ESPECIALLY FOR LADIES AND MISSES.

We are just in receipt of the first lot of small-sized watches designed especially for school-teachers or little girls. I have often thought that, when the boys were getting so much enjoyment and real profit by having a watch that would keep time for a very small amount of money, it was a pity that their sisters could not have one just a little smaller, to help them to be prompt and energetic. Well, friends, we have got it. It is a perfect little daisy—only 1½ inches in diameter, stem-winding and stem-setting. In this latter respect the girls will have a big advantage over boys. It is also short-wind, and won't take all the time a girl or boy can spare before breakfast time to get his watch wound up. Then if our little friend should forget to wind it every morning, and let it run down, she can set it with the family clock by simply pushing in the winder which turns the hands, instead of winding the watch. When I was in the jewelry business, if I could have offered such a watch to school-teachers for \$10.00 I should have called it wonderfully reasonable. The price of this little watch is only \$4.00. Sent by mail, registered, post-paid, for 15 cts. extra. Now, then, my friend, if you have got a good little girl at your house to whom you wish to make a good and useful present, I do not know of any thing in the whole wide world that will hit the nail right squarely on the head like the misses' Waterbury. When you order it, be sure to say "Letter L." Letter J is exactly like the one I have just described, only it has a second-hand, and is the size of the ordinary Waterbury—2½ inches across, and is the same price, \$4.00.

CONVENTION NOTICE.

The Northeastern Ohio, Northwestern Pennsylvania, and Western New York Bee-keepers' Association will hold its tenth annual convention in City Hall, Franklin, Pa., Wednesday and Thursday, January 30th and 31st, 1890. Good hotel accommodations have been secured at \$1.00 per day. C. H. COOK, Sec'y., New Lyme, O.

PRICE LISTS RECEIVED.

Price lists for 1889 have been received as follows:
D. Kaufman, Needy, Oregon. Bees and queens.
W. D. Soper, Jackson, Mich., an 18-page list of bee-supplies.
F. H. Cook, Andover, Ct. Club list to bee-keepers.
M. H. Hunt, Bell Branch, Mich. Bee-keepers' supplies.
We have just printed for S. H. Colwick, Norse, Texas, a four-page price list of bees and queens.
We have also just printed Paul L. Viallon's eleventh annual price list of bee-hives, etc. Bayou Genla, La.
We have now in press a catalogue of articles pertaining to the bee-business, for G. E. Hilton, Fremont, Mich.

DADANT'S FOUNDATION FACTORY, WHOLESALE AND RETAIL. See advertisement in another column

Vol. XVII.

JANUARY 15, 1889.

No. 2.

TERMS: \$1.00 PER ANNUM IN ADVANCE; 2 Copies for \$1.90; 3 for \$2.75; 5 for \$4.00; 10 or more, 75 cts. each. Single number, 5 cts. Additions to clubs may be made at club rates. Above are all to be sent to ONE POSTOFFICE.

Established in 1873.

PUBLISHED SEMI-MONTHLY BY

A. I. ROOT, MEDINA, OHIO.

Copies to different postoffices, NOT LESS than 30 cts. each. Sent postpaid, in the U. S. and Canada. To all other countries of the Universal Postal Union, 18 cts. per year extra. To all countries not of the U. P. U., 22 cts. per year extra.

BEE-CAVES VS. HOUSE-CELLARS FOR WINTERING BEES.

SOME THOUGHTS ON QUERIES NO. 94, 95, AND 96.

CELLAR wintering of bees has come to be quite an absorbing thought in the minds of all apiarists living north of latitude 40°, and, in my opinion, whoever lives in the year 2000 will see nearly if not all colonies of bees then existing north of this degree of latitude, wintered in an underground repository. If this is to be so, it is of some moment that the ideas which are now assuming form on this subject be turned into the right channel. Why I make the prophesy as above is, that, with each succeeding year, the timber land of our country is growing less and less; so that, when the year 2000 comes, very few if any of the forests which now exist here at the North will be allowed to stand. In these forests have been our protection from the extreme cold which now is beginning to be experienced in many localities where the timber is already becoming scarce. This timber is of a twofold protection against cold: First, it holds the water in the ground so that many springs exist which otherwise would not; and these springs, where they abound, modify the air to a much larger extent than many suppose; and, second, the force of the wind is broken, so that, when a warm day appears, the bees in a sunny nook out of the wind can get a nice flight, while those in an exposed situation can do no such thing. Thirty-five years ago there was scarcely a winter when bees could not fly as often as once in six weeks; and our mill on the stream which runs, or used to run, about 50 rods from where I live, was run by

water nearly every day in the year. Now we often have from four to five months in which the bees can not fly, and the mill is run nearly if not quite half of the time with steam, on account of lack of water. I used to leave two-thirds of my bees on their summer stands, putting the other third in the cellar; now I put two-thirds of them in the cellar, leaving the other third out, packing them for winter in the best possible manner; yet, with all of my care, the cellar seems to be winning favor with each succeeding year.

Now, aside from the causes given above, there is another reason why the cellar is gaining in favor. When I first began to winter bees in the cellar I used one under the house, while now I use one entirely away from any building; and this latter is so much superior to the former that it is winning my affections altogether. In what is it superior to the former? Chiefly in the temperature being entirely controlled without any interference of mine during the whole time that the bees are in their winter quarters. In answering query 94, Dr. Miller and Mrs. Harrison are favorable to a warm room overhead, presumably to keep the cellar warm; while in Query 95, both are compelled to lower the temperature by carrying in ice or otherwise. Now, this is just where a cellar under a superstructure fails. Just in so far as a warm room is of advantage in extreme cold weather, it is of positive disadvantage in a warm spell in winter. Who wants to be obliged to keep a fire in or over a cellar all winter, every time the mercury sinks to zero, or open all doors and windows which the cellar contains, carry in ice and what not, every time the mercury rises to 50° or 60° above zero? And even after we

have had all of this trouble, our pets are not nearly as well off as they would have been had the temperature kept evenly at 45°. Of course, where one has no other place in which to winter bees, he must do the best he can with what he has got; but the point which I object to is, the recommending of any thing which requires so much fussing and anxiety of thought, above something which requires nothing of the kind, and over one, which, after a thorough trial by even the most prejudiced, would be recommended as much superior to the old way.

At Query 94, Dadant & Son "hit the nail on the head" when they say there is no difference, if the temperature can be kept the same; and George Grimm certainly misses it where he says, "The matter of living-rooms above cuts no figure." For many years before I moved to where I now live, I wintered my bees in the cellar under the house we lived in; and during nearly every one of these winters there would come times when I had to build a fire in this cellar to keep it warm enough, or else open the doors at night, or carry in snow or ice, or both to keep it cool enough. Several times it kept so warm that there was no snow or ice to be had, and the outside air during the night was warmer than the air in the cellar; then I had such a state of affairs as friend A. I. Root has often feared he might have were he to try cellar wintering—a time which "tried men's souls;" or, in other words, a time when there was a general "roaring," such as Query No. 95 wants to know about. At such times Query 96 is very pertinent; for in a perfectly dark cellar is our only salvation. L. C. Root says, in answer to No. 95, "The room should be so arranged and managed as to avoid these causes of uneasiness." If I were back to where I should be obliged to winter bees in that cellar again, I would willingly give him \$500 to tell me how to so arrange and manage in such times as spoken of above; for candidly I do not know how to do it. Since I built the special repository which I now have, which was fully described and illustrated in GLEANINGS of last year, the temperature inside, while the bees were in it, has never been lower than 40° nor higher than 48, with the exception of the winter when I kept the temperature up with the oil-stove, which resulted in almost a total loss, as most of the readers of GLEANINGS will remember; and since I shut off all ventilation, which Prof. Cook and others think necessary, as their reply to these queries would denote, the temperature has not been lower than 43° or above 46°. A properly constructed underground cellar, with no building above it, is self-regulating, and of itself sufficient to carry bees safely through the winter, no matter how much the temperature may change outside; and, if I am correct in my opinion, it will be the chief way of wintering bees in the near future.

Borodino, N. Y., Jan. 1, 1889. G. M. DOOLITTLE.

Friend Doolittle, I am very much obliged to you for having contrasted these two forms of wintering-repositories. As Captain Hetherington, P. H. Elwood, and others in their neighborhood, have made some careful and extensive outdoor arrangements for wintering bees, I should be glad to know if their decision corroborates this. If I had a sandy or gravelly side hill, I would start forthwith—yes, right in the month of January, to make such a cave as you speak of, for various purposes. I am a little surpris-

ed, however, that you maintain a temperature as low as from 43 to 46. The temperature of the Manitou cavern, away up on the top of the mountain, in the neighborhood of Pike's Peak, is 52°, winter and summer. I am going to have a lot to say about it before I get through with my Notes of Travel. Mammoth Cave, in Kentucky, is 56°. Perhaps you have told us the temperature of your cave in the summer time. If so, I have forgotten it. But I do not see how it can be below 50°, unless the outside temperature of the winters keeps it down. Can we have some reports from others who have caves and similar places? Would it do to shut up a cellar tight, in a damp clay soil?

GLASS SECTIONS.

SOMETHING FROM ONE OF THE FRIENDS ACROSS THE WATER.

DEAR MR. ROOT:—Will you kindly say if you noticed in an article in the *British Bee Journal* of the issue of Oct. 4, 1888, my remarks on glass sections. I shall be glad to hear what you and the Americans think of these. I might also say I have had some glass sections made from round honey-bottles. I took my glass-cutter and cut slices off the bottles, as shown in the accompanying sketch. It was difficult to cut the bottles, but I succeeded in making sufficient to try what I wanted. The black lines will show where the cutter was applied. I took two slices for each section, placed a small sheet of wax foundation between these slices, and, behold, the foundation was firmly fixed in a moment! Next each section was placed in a frame very similar to what was illustrated in GLEANINGS about six or eight weeks ago, and shown again herewith.

HOW TO MAKE GLASS SECTIONS.

I use Heddon's wide frames, and I had a frame made to hold four glass sections. These sections looked lovely. I had them beautifully sealed over—not a single "pop-hole" in any of them. The above block was made so that it could be pushed into one of Heddon's frames. Was it not curious, that a similar idea should occur about the same time to your correspondent Rambler and myself? He used strips of wood, or shavings, instead of glass rings. I think glass cells might be cheaply cast or manufactured, and they would look very attractive. I hope you will not say there is nothing like leather; wood sections are best because, etc. To clean the glass cells or rims, simply boil them—they may be used over and over again.

LANGSTROTH'S PICTURE.

Please do not tell Rev. Mr. Langstroth that I say the portrait on page 843 is one of a fine-looking man. I am sure America should be proud of the looks

only. I have seen very few finer-looking Englishmen. There is only one likeness that dwells in my mind, and that is Dr. Livingstone. Doubtless you will say Mr. Langstroth is too wise to be made vain.

T. BONNER CHAMBERS, F. L. S.

Tref Eglwys, Caersws,

Montgomeryshire, England, Nov. 20, 1888.

Friend B., we have noticed what you say about the glass sections; but unless it is for something fancy, or for a curiosity, we should pronounce them altogether too frail; and glass cut out of bottles, as you mention, is terribly dangerous stuff for almost anybody to handle. The objection to circular sections is the amount of waste space between the circles. If they are to be used, I think I should much prefer stiff paper or wood shavings.

THE APPLE-TREE BARK-LOUSE.

IT HAS MADE ITS WAY CLEAR TO TASMANIA.

LIKE GLEANINGS very much, especially the articles written by Prof. Cook. They are really instructive and interesting. I have his book, "Injurious Insects." We are sorely troubled in this part by the apple-tree bark-louse, *Mytilaspis conchiformis*. I have sprayed some of my trees three times with strong soapsuds, also with soft soap, and still I see some alive. It may be I am too early, and they still keep hatching out. Like yourself, I should like to know more than Prof. Cook tells us about this insect. It seems to be the female that becomes fixed to the bark. Can he tell us anything about the male, and what is the latest and best method of destroying this pest?

W. P. CLENNETT.

Port Esperance, Tasmania, Nov. 19, 1888.

Prof. Cook replies to this as follows:

As Mr. Clennett writes from Tasmania, it seems that even scale insects which are poorly prepared by nature to make journeys have circumnavigated the earth. In this case, man has doubtless carried this pest to the other side of the globe. How fortunate if we could know of such terrible enemies, and not, through our ignorance, scatter them to blight the prospects of our antipodes! This louse is now known to science as *Mytilaspis pomorum*. When the female is fully mature—August in Michigan—she looks any thing but animate. She is then but a mere scale, somewhat the shape of an oyster-shell, but slim, usually curved, and a little darker than the bark of the tree or twig on which she rests, and to which she is attached. This scale is only about one-fifth of an inch long. Late in August, if we carefully raise this scale with the point of a knife-blade we shall see what appears to be a white dust. When this is magnified we note scores of white oblong eggs. These eggs hatch early the following June. The young newly hatched lice are oblong, yellow, very small, and active. Soon these insert their long slim beak, or sucking-tube, and settle down on the tender bark, not on the leaves, as does the young tulip and maple bark-louse. These minute active lice may be blown from one tree to another, or may crawl on to the feet of some bird, and be carried to another tree. This is the only time in the life of the insect when it can be scattered from tree to tree. The louse, when once fixed, grows rapidly, becomes scale-like by a secretion, and by August is mature, and lays its

eggs. When numerous they are very destructive. I have seen many fine apple-trees ruined by them. There are very few if any males. The males of bark or scale lice that have been discovered are two-winged. It seems likely that there are often no males in this species, and reproduction is agamic, as in case of drone-bees. We see now how these pests may be carried from one country to another. If we carry the trees containing the lice at any season, we also must carry the lice.

The best remedy is to rub the trunk and limbs of affected trees with soft soap, or, better, a mixture made as follows: Heat one quart of soft soap or one-fourth pound hard soap, with two gallons of water. When hot, thoroughly stir in one pint of crude carbolic acid. By use of a cloth, with sleeves rolled up, thoroughly rub the twigs and trunk. Do not wet the foliage any more than is absolutely necessary. This is to be done just as the lice hatch, which, in Michigan, is early in June. In Tasmania it would be at a very different season. By carefully raising the scales we may easily discover the exact time. It is just when the white eggs begin to go, and the minute yellow lice to come.

Agricultural College, Mich.

A. J. COOK.

APIARIAN EXHIBITS AT FAIRS.

HOW THEY MAY BE MADE TO PAY.

I WISH to add a few words to what has already been said in regard to making honey-exhibits at county fairs. In looking over the answers to Question No. 79 as to whether it pays or not, I find the greater part of them are in the negative. Now, I have been taking some stock in county fairs this fall, more for the purpose of advertising than for securing premiums, as only one out of four which I attended offered premiums in the apiarian line, except for the best 5 lbs. of honey in the comb, which was not much of an inducement for premiums. I am confident that it has paid well for the time and money spent. While on the fairgrounds I took orders enough for honey, at remunerative prices, to amply pay me for my time and expense, besides building up a home market for all that I shall have to sell this season, and perhaps another. I am confident that the demand will increase. My display of honey was not large, but it was very fine, and attracted more attention than any exhibit in the halls, consequently the officers of the association insisted that I should come back again, and promised to add an apiarian department to their premium lists if I would send them a form of what was needed. This reminds me of friend Poppleton's suggestion; i. e., that you publish in GLEANINGS some of the best lists in the apiarian department, suitable for county fairs, for the benefit of those interested.

We did not get any surplus honey in this locality until Spanish needle and heart's-ease, or, better known here as smartweed (and perhaps both), began to bloom, which was about the 20th of August. Then as soon as the honey began to come in pretty freely our bees took the swarming fever, and then swarm they would, queen-cells or not, in spite of all we could do, till about the 10th of September. The consequence, as you may surmise, was a light crop of honey, which was quite a disappointment, as it was the first and only good honey-flow we have had for two years. I had two swarms on the 8th of Sep-

tember, which I put on empty combs, and they very nearly filled their brood-chambers with honey, and have an abundance to keep them through the winter. I also had plenty of drones flying the 1st of November, and I think they would fly yet if it were warm enough, as I am confident that a part of my colonies have not killed their drones yet. Is not this very uncommon as late in the season as this?

WILLIAM HUTCHISON.

Benton, Ills., Nov. 29, 1888.

Friend H., we are glad of your report in regard to exhibits at fairs, as well as of your late comb honey. If the winter is as mild with you as it is with us now (Jan. 12), it will be nothing strange if the bees should keep the drones until spring.

MAKING GARDEN IN JANUARY.

HOW MUCH OF IT CAN WE DO PROFITABLY?

WELL, friends, the field of operations for winter gardening is broadening and enlarging year by year—not only in Florida and California and other favored localities, but right here in the North. The list of seeds and plants, so far as my knowledge extends, may be summed up as follows: Asparagus, early beets, early carrots, celery, cress, cucumbers to some extent, lettuce, onions (especially the Egyptian, or winter onion), parsley, radishes, rhubarb, and last, but by no means least, spinach. Asparagus requires considerable preparation beforehand. We must get good strong roots by growing them in the open ground, and then by the first of January, or earlier, put our sash over them right where they stand. Beets, spinach, onions, kale, and other like hardy plants, that will grow at a very low temperature, can be started from the seed in cold-frames or cold greenhouses. If your locality is sheltered, and you have straw mats and shutters to cover the sash, quite a growth may be made in January, without the use of fire heat at all. As handling sash, mats, and shutters is laborious work, I would by all means, as soon as I could afford it, have a cold greenhouse. With the usual apparatus for raising the sash, one man can raise and lower one whole side of a greenhouse 11x30 in three minutes, and without working hard either. During this present winter we have been using three machines, made by Hitchings & Co. These machines cost about \$10.00 each, and I never enjoyed any work more than I do raising and lowering the sash to control the temperature. I do not have to call in any boys to help me, and I can leave the sash at any angle I choose, and there is no danger from being blown down by the wind, even if we have a very high one, for each one of the sash is held rigidly by means of iron rods, just where I leave it until I come around and choose to move it.

Under these sashes, without any fire heat at all, spinach, beets, and radishes have come up and made a very fair growth, and that, too, during the very shortest days in the year. I am especially pleased with the behavior of spinach under glass. It is about as hardy as winter rye, and seems to

grow all the time, when the ground is not freezing, even outdoors. Our main crop of spinach was planted out in the open fields, in September; and although it has had, up to the present date, Jan. 10, no mulching at all, the great bushy clumps of foliage are almost perfect. Some of the larger leaves have been frosted a little. Whenever the ground is not frozen we just go out and cut the roots off below the surface of the ground, throwing the heads into a large basket. It is then washed, and the poorest outside leaves pulled off, and then it is ready to cook. Cook it about as you would green peas, and I think it is almost if not quite equal to asparagus. We are retailing it in our town at 10 cts. a pound, and it is now selling at a very satisfactory rate. You may ask why I take the trouble to put it under glass, if it flourishes so well outdoors. Well, we are usually able to have it in nice order outdoors from Jan. 1 to the middle of February. After that, the frequent freezing and thawing often spoils it. By having a fine crop under glass, you can get it at any time when you can't get the other, and we are sure of it clear along into March.

Kale is raised and cooked very much like spinach. You can use your plants right from the cold-frame where they are grown, or you can have large heads started in the summer time, to be out during winter, from the open ground.

The Early French forcing carrots will stand about as much cold as lettuce, therefore in our locality it must be raised under glass. It is sold in little bunches, and is used for flavoring soups.

Now is the time to plant seeds of celery for your first crop. We prefer the White Plume; but we are this year making a test of the Golden Self-blanching. A good many ask why we commence so very early. My reply is, because we want to have the first in the market. Celery in June will generally command a good price, and I have never found the plants too large to put out in the field. Last year we had one bed of transplanted plants that were not called for when the plants got to be a foot high, and perhaps as large as your wrist. I feared they were too large to stand transplanting, but concluded to try them. When the celery was dug and put away in November, these plants had produced the finest stalks we had in the field. They bore the transplanting, and started right out to grow, quicker than any of the small ones; and it has been the case so invariably that we expect this season to do quite a trade in extra-early and extra-large plants. It is true, there has been some trouble with White Plume celery running to seed, when started very early. Here is a letter right to the point:

Mr. Root:—In a seed and plant circular received from you, you speak of offering for sale celery-plants from seed sown in January. Now, suppose a person were to purchase a quantity of these plants, and they were all to run to seed. A friend had his early planting (consisting of about 7500 plants) go to seed for two years in succession, while that from seed sown in the middle of March

made a fine crop. The point is, Has a customer any security at all, that celery plants grown from seed sown as early as January, will not go to seed?

Kingston, Pa., Dec. 12, 1888.

M. GARRAHAN.

Friend G., there is something about this business of going to seed that I do not quite understand. We have had some trouble in our own grounds, but not very much; but as extra-early plants are much more likely to run up to seed, we go over the field as soon as the plants begin to grow, and pull out every one that has started to send up a seed-stalk, as if it were a weed. The whole number of such in our early celery has never amounted to more than ten per cent. A few who have purchased plants of us have complained that the greater part of them ran up to seed. Last season we had one lot of Golden Dwarf celery of which a great part sent up seed-stalks in the plant-bed before it had been planted out at all. We burned up all the seed we had on hand, and pulled out all the plants that showed seed-stalks, and threw them away. As no more started to shoot up, we put the rest out in the field, and they gave us splendid celery. I wrote to the seed-grower who furnished us the seed, and he said the same lot of seed had given excellent results in the hands of others. From this and other similar reports I am inclined to think it is something in the treatment of the plants rather than the fault of the seed; but just what treatment makes celery send up seed-stalks, I can not tell.

If one were to *save his seed* from these plants that shoot up so prematurely, the seed would, without question, be worthless; but any seedsman who has any regard at all for his reputation would be careful that none of his seed come from this source. When I was visiting at Peter Henderson's two years ago, one of his neighbors told me they found the White Plume celery entirely worthless, because so much of it shot up to seed instead of making celery. He said his seed came from Peter Henderson. I think few if any of Henderson's other customers have experienced a like trouble.

Cress, or pepper-grass, can be sold in limited quantities along with lettuce and radishes, so as to pay a good price. It is also quite hardy.

Cucumbers and tomatoes can be raised in greenhouses, but it is something like strawberries, I opine. Few of us have a greenhouse that will give just the temperature and other conditions to make a success of it. Lettuce will do nicely in cold-frames, without heat, especially if you start in the last part of January or later. I suppose most of you will start your Grand Rapids lettuce during this month. The Grand Rapids and Boston Market lettuce are the only two kinds we have succeeded well with when grown under glass. One special quality of the Grand Rapids lettuce is its silvery whiteness; but this is better secured by the assistance of heat of some kind; for to have it white it must be grown rapidly. If you make a greenhouse 11x30 feet on the plan I have suggested, I would have a shed, with a permanent roof at one end. You will remember that our friend Eugene Davis, the

originator of the Grand Rapids lettuce, directs that the house be placed so as to run from the northwest to the southeast; then put your shed on the northwest end, and it will never shade the other part. Well, if you do not propose using fire heat, you can have some heaps of manure in this shed, for making hot-beds, and the fermenting manure will help keep up the temperature. By making your shed a little longer you can keep celery beautifully on the extreme north end. During warm weather, when there is no danger of frost, you can remove the straw that covers it; and by allowing it to grow slowly it will be fit for use clear into March. Opening and closing the ventilators of your cold greenhouses will give the celery the proper amount of air, and you are not likely to let the celery freeze if you watch your plants in the greenhouses. I presume a *hot-bed* would give finer Grand Rapids lettuce than you would get by any other means.

If you have any onions that trouble you by sprouting, plant them out close together in your cold greenhouse, and they will sell nicely for bunch onions in January and February. At this season of the year we get five cents for one-third of a pound of bunch onions; that is, we divide a pound into three bunches. A few clumps of parsley put into your greenhouse will give you small bunches for flavoring soups all winter long.

SUB-EARTH VENTILATORS.

DR. C. C. MILLER RECONSIDERS THE QUESTION
AS DISCUSSED ON PAGE 26.

AT the close of the Question Box for Jan. 1, the editor remarks, "Surely our veterans can get very much nearer the truth than the average beginner, who proposes to winter bees in the cellar, can guess at it." I think that applies to Questions 97 and 99. The beginner would be a little bewildered over the answers to 98. Of the twelve who reply, only five say they have tried sub-ventilators, and four of these five think them advantageous, while the fifth thinks them useless. Two of the 12 have never tried them, and give no opinion as to their merits; indeed, I suppose three may be counted in this list, if Dadant & Son be counted there. Of the remaining four who do not claim any experience with them, one thinks them not worth their cost; one thinks all the ventilation needed can be had otherwise; one thinks them objectionable if other conditions be right; and one is quite certain they are worse than useless. The editors say, "We hardly know how to account for the difference in testimony in regard to the value of these ventilators, unless," etc. Good friends, there is more difference in opinions than in testimony; for, if I mistake not, Doolittle is the only one who gives any *testimony* against them. It is only fair, however, to say that Prof. Cook, if I mistake not, places no value on sub-ventilators as a means of ventilation, only as a cheap means of regulating temperature.

The beginner, however, who reads over the replies will be likely to get the impression that it is of no great importance to pay any attention to the matter of ventilation; and friend Hutchinson, in a late number of the *Review*, specially devoted to

ventilation, concluded that his contributors agreed in that view, although I did not suppose my own contribution could be counted on that side. If a beginner, however, were to ask me about it, I should say that, although many were successful who paid no attention to ventilation whatever, yet the fact remained that ventilation must be considered a matter of vital importance. Very few would dispute this in practice, even if they should in theory; for many of those who pay no attention to the ventilation of cellars are very particular as to the ventilation of hives in the cellar. It requires very little reasoning to show that it is useless to ventilate a *hive* if the *cellar* be not ventilated. The only question is, Does your cellar take care of its own ventilation without any effort on your part? I suspect there is great difference in this respect. A cellar whose walls are full of cracks, or which are made of porous material, may receive through such walls enough fresh air to need no care from its owner. Even in that case it is possible that a sub-ventilator might pay well by way of keeping up temperature. If, with no special care, the temperature keeps up to 40° or 45° in the cellar, and the air is at all times fresh and sweet—and there may be many such cellars—then I should hardly consider a sub-ventilator advisable. But suppose the thermometer outdoors has the sportive habit of coquetting around among the twenties and thirties below zero, making the air in the cellar go down to freezing, then, although the air may be *pure* enough it is not *warm* enough, and it may cost a good deal less to warm the air by having it come through a sub-ventilator than to warm it in any other way.

Cellaring bees is practiced only where it is cold, and probably there is no reason for it, other than the greater warmth in the cellar. Where the winters never send the mercury below the freezing-point, no one thinks of cellaring. Even where the thermometer sometimes goes 20 to 40° below what is considered the best temperature for the cellar, outdoor wintering is preferred. Now, why? The answer probably will be, that the bees in such a climate will have a chance to fly at times, if outdoors, and in the cellar the confinement will be longer; and, besides, the bees will get too warm, and be uneasy in the cellar if the temperature gets above 50°. Yes, but it doesn't do the bees any hurt, nor make them uneasy, to have the thermometer go up to 55 or 60° outdoors, even if it is in the night, and they can't fly, and we can even up the other part by carrying out the bees for a fly every time the bees outdoors have a fly. No, the warmest advocates of cellaring, and those who insist that no ventilation is needed, would, I think, insist that, in a mild climate, even if you give the bees the same fly, and never allow the cellar to become too warm, they will winter better out. Now, if there is any other reason than because the air is better outdoors, will some one please tell me what it is? The fact is, there is a density of ignorance regarding the value of fresh air for man, beast, and insect; and I advise each one to experiment a little for himself and see if *his* cellar is one of the kind that lets in enough air when every thing is tight shut.

C. C. MILLER.

Marengo, Ill., Jan., 1889.

Friend M., in G. M. Doolittle's article in this present issue you will notice that he discusses cellars versus bee-caves. Well, his

bee-cave has an advantage over most cellars in having from three to four feet of dry dirt over the most exposed portion. This dry dirt is covered with a roof, so it is always dry; and there is enough of it so that no frost ever gets through to the bee-cellar. Now, I am inclined to think that this dry dirt overhead affords all the ventilation needed, and it may be the very best ventilation, therefore no sub-earth ventilator is used. In ordinary cellars, however, and perhaps in many bee-caves, the frost would get through enough so that a sub-earth ventilator might be of very great use in keeping down the temperature, as you express it.

In regard to your last point, as to why bees are better off outdoors than they are in the cellar, I should answer, For the simple reason that anybody or any thing having life is better off outdoors than in a cellar; yes, better off outdoors than in a house. Remember what I said about the health of the negroes in the South. Outdoors we have the kind of ventilation that God made; but in a cellar or in a bee-house, we have such as man provides. For a few weeks back, I have been having a great deal of enjoyment in manipulating the immense ventilators of our new greenhouse. Whenever the thermometer is above 40° outdoors, the large ventilators are swung wide open by the aid of the proper machinery. The consequence is, that my plants have had almost as good ventilation as if they were entirely outdoors all the while, and at the same time they have been protected entirely from the frost, clear up to the present time, Jan. 10. The plants have now an excellent color, and they are hardy and robust, but they do not grow nearly as rapidly as if I kept them warmer. The quality of my plants in the spring will certainly be superior; but our lettuce grows so slowly that we shall not have any fit to cut before February. I presume that, if the ventilation of the cellar were just as good as it is outdoors, the bees would stay in their hives, and behave themselves just as well as they do outdoors; and I think I have wintered a hive or two in the cellar when they were just as quiet, and stayed in their hives just as well as those out of doors did; but when I had a large number in the cellar, especially when some of them were rousing strong colonies, they crawled out of their hives and smelled bad, and acted fearfully; in fact, the only way I could keep them in their hives was to make the cellar so cold as to freeze them back when they came out at the entrance; and a good many times they would come out, even with the temperature below 40°. They acted just as if they came out and died, solely to be contrary. I don't believe that I ever want any more bees in the cellar, here in our locality. By the way, Ernest has one colony of bees in a Heddon hive in ^{his} cellar, during this unusually warm winter. The Heddon hive is so shallow he did not like to risk it outdoors with the frost. Well, they are wintering nicely so far, and they behave themselves nicely, and as well as the bees do outdoors. Of course, he keeps the cellar dark.

DOT GOMING BEE.

BY EUGENE SECOR.

I schpect you haf read of dot zhust goming bee
 Vhat dose Yankees haf got poorty kvick,—
 Dose bees vhat run ofer my sehlow Zherman blacks,
 Und nefer kvits vork gause dier sick?
 I dinks, when I hears of dose schmart Yankee bees
 Dot zhust vone vill be all vat I need,
 Begause dem haf dongues like dot schmall honey-
 bird,
 Und suck up vone kvart mit a feed!

But Yankees, dem brag of dier goundree so pig,
 Und dier bolidics so *awful* much,—
 Of dier horses vhat run mit der lightnig away,
 Und dier peautiful vimins, und such,—
 Dot I more dan twice believe ven dot bee *does* been
 gome
 He'll schpeak so ve Deitchers gan read;
 Und if him don't got to be all ofer plack,
 I dinks him vill *show der plack seed*.

But I laffs ven I reads of dot schmart goming bee,
 Ven I dinks of Hans Brinkerhoff's mule—
 (Hans vas mine neighbor zhust ofer der vay,
 Vere him lives mit der golden-like rule).
 Vell, Hans him leadt oudt dot donkey vone day,
 An der pump to gif him some drhink,
 Ven up zhump vone pig in der mua mit der trough,
 Und oudt skibbed dot mule in a vink.

Und schtraight mit der bee-line, und halter to boot,
 Dot donkey, he schtart for mine lot
 Vere a hundred bee-boxes schootd all in some rows:
 "Mebbe dems oats"—und mebbe so not—
 Ven all at vone dime him schtopped at vone box,
 Und schmelled a loudt schmeil in dot hole
 Vere dose bees make dier honig und likewise wax—
 You den should hear dot schmile him schmole.

But dot olt king-bee vas daking vone schleep,
 Und vas mad ven dot racket him hear;
 He tought er prass pant had zhust broke out loose,
 Or some oder loudt noises vats kveer:
 So oudt him send scouds to see vat vas up,
 Und den der grant circus vas gome—
 Der more of dose bees vot go for dot mule,
 Der kvicker dot mule don't go home.

Ven tree or four hundert glimbed into dose ears,
 Dot donkey, him right apout face,
 Und lifted vone foot, und den lifted two,
 Like one horses vat wanted some race;
 But he don't gone pack to dot dear old home
 Vere Hans vas been calling so sweet,
 But he lifted dose boxes so handy und kvick,
 Und gave dem a good schtart—mit his feet.

But dot goming bee vas arrived all der dime,
 Und gloser dan vone broder schtiks
 Aroundt dot donkey vot hadn't got learned
 To nefer kick against der pricks.
 Dot donkey, him laff on dot oder mout side,
 Ven him gets all him vants of dot fun;
 Him gry like vone *baby*, und rolls mit der grass,
 Und den him zhump up und home run.

Dot donkey, him svelt oudt like Zhumbo vas vide,
 Und I dinks Hans don't go to feed
 Him any more oats so long as him liffs
 To make him so fat as he need.
 Und I peelf dot Hans vill gome ofer und buy
 Dose bees vot is petter dan gorn
 To fat up dose mules, und make dem home schtay
 Gondended und tame mit der barn.

FIXING FOR HONEY-EXHIBITS AT FAIRS.

DR. MASON GIVES US SOME IMPORTANT SUGGESTIONS AND DIRECTIONS IN THE MATTER.

FRIEND ROOT:—I have received several inquiries, within the past few days, for suggestions in regard to exhibits of bees, honey, etc., at fairs, and plans for buildings for such exhibits; and as each one seems to be a reader of GLEANINGS, I thought it would be a good plan, for me at least, to reply through GLEANINGS, if "Barkis is willin'."

Only one, Mr. J. C. Graham, of Missouri, has inclosed a stamp for reply. I should very much dislike to be obliged to feel that bee-keepers are "stingy," but it has become quite a nuisance in my case. I am a busy, poor man, and don't care to give my time, furnish paper and envelopes, and pay postage, for the privilege (?) of answering correspondence that is of interest only to those who ask. "So, there now."

At some of the large fairs a separate building for the use of bee-keepers seems to be a necessity. At others, plenty of room can be had in buildings with other exhibits. In some localities where there are large fairs, there are not enough bee-keepers interested in a honey-exhibit to make a respectable display.

The size of a building will depend upon how large an exhibit is to be made. The bee-keepers' building at the Ohio Centennial last fall was 36 x 80, and was just right; but had the past season been a good one for honey, it would not have been one-fourth as large as needed. At our Tri-State Fair here at Toledo, the space usually occupied is equivalent to about 6x70 feet.

For a building, I should prefer one from 30 to 36 feet, wide and as long as would probably be needed. An exhibit of from 500 to 600 pounds of extracted honey in glass, with Muth's honey-jars and other small glass receptacles holding from half a pound to three pounds, can be made to occupy a space of 6 or 7 by 20 feet, if put on shelves, and

from 400 to 500 lbs. of comb honey in one-pound sections in crates would occupy the same space. More could be used to good advantage, and less could be made to do nicely, very much depending upon the taste of the one arranging the display. A building 60 feet long would accommodate only six such exhibits.

A building modeled after either of the following diagrams will be found quite convenient and satisfactory.

DIAGRAMS OF GROUND PLANS FOR AN EXHIBIT BUILDING.

In each diagram, A represents platforms 2 feet high and 7 feet wide, boarded up from the platforms to the ground or floor; B, platforms 6 feet wide and 1 foot high on which to exhibit extractors, hives, etc; C, passageways 6 ft. wide; D, doors, $3\frac{1}{2}$ to 4 ft. wide; E, double doors, each door 3 feet wide. All the doors are to be hung on the sides of the building, and open out. The doors at D are to be fastened to the posts, by hooks on the inside. One door is to be furnished with a lock, so as to be fastened from the outside if desired. Under the platforms A, should be several doors, so that boxes, etc., in which honey has been taken to the fair may be safely stored away out of sight.

ARRANGEMENT OF SHELVING FOR HONEY-EXHIBITS IN GLASS.

The sides of the building should be 8 or 9 feet high above the platforms. Eight feet will do nicely, but 9 feet will give room for a display of honey-plants, flags, etc., on the walls back of and above

the honey. Light should be admitted through large windows in the roof. For this size of building, 4 windows, about 5 feet wide and 6 feet long, would be about right. The windows should be so arranged that bees can escape at each end; for if there are any bees in the vicinity, many of them will be sure to get into the building. The platforms should be made very firm and solid, for honey is quite heavy, as every one knows.

At the Ohio centennial it was left for each exhibitor to arrange his exhibit to suit his own fancy, and every one put up shelving; but a portion of my exhibit was on a pyramid. If shelving is used for extracted honey, a very good way is to make some "risers," as shown in the engraving below.

Place the foot of the riser about 2 feet from the front edge of the platform, and have the first, or lower shelf, 18 inches* from the platform, and so on as shown. Board up under the lower shelf, but not under the others, unless preferred. When complete, cover all with strong white paper, or muslin. The top of the risers will be a foot more or less from the side of the building, and can be supported there by a piece of board.

If any of the exhibitors live so far from the exhibition grounds that it is inconvenient or impossible to go home each night, and they wish to curtail expenses, and have a good time, just take along a straw tick and some blankets; fill the "tick" with straw on the grounds, and make a good bed behind the shelving. If still more independence is desired, take along a good-sized box, filled with such things as will "minister to the wants of the inner man;" and if you are not happy it won't be my fault, for "I've been there," and know how it goes; for although I live but a mile from our Tri-State Fairgrounds I sometimes stay in the building over night with the exhibitors for the sake of the visit. As the time is near at hand when the premium lists are made up by the officers, or others in connection with the management of fairs, it is important that some bee-keeper in each locality see to it that the bee-keeping industry be not overlooked. Look well also to the matter of a judge, or judges. At every exhibition of bees, honey, etc., that I have attended, I should have been willing to have the exhibitors act as judges, and I believe there are not many competent judges who have not been good exhibitors; or perhaps it might better be put this way—not many good exhibitors who are not good judges.

Auburndale, Ohio.

A. B. MASON.

Now, look here, doctor. I don't want you to abuse our friends because they don't put in a stamp. Make your answers to all such queries and forward them to us, and we will credit you enough for your trouble to cover postage, and may be a little something more. We want the friends all to understand, however, that they are not to expect a reply—they must look for it through the bee-journals. Where a direct reply is wished for on some pressing matter, they should by all means inclose a stamp—or, better still, a stamped envelope. If the question is a brief one, inclose a postal card directed to yourself, and then say in your letter, "Please reply on the inclosed postal card." And I think it is an excellent idea.

* The engraving at this point is not strictly correct. The first step should rise 18 instead of 9, as shown, and should retreat more from the edge of the platform.—[Ed.]

for people who ask many questions, to have some postal cards printed, with their addresses on them. Even a busy man will seldom refuse to take a pencil and scratch some kind of an answer on a postal.—Your suggestions in regard to fixing for honey-exhibits at fairs are excellent, and I do not know of anybody in my whole circle of friends who is better prepared to make suggestions than yourself.—Your concluding remark is tiptop. It gives us a glimpse of the good time coming, when there will be no more quarreling about who ought to have the premiums, and calling hard names.—We should be very glad of some more suggestions in regard to arranging for honey-exhibits at fairs, with simple sketches to illustrate the plans.

THE TIGER BEETLES.

A CURIOUS LAW IN MIMICRY.

I AM receiving so many kind words regarding my articles in GLEANINGS on general entomology, that I feel very much pleased, and encouraged to go on. As we often say, the time seems ripe for just such articles. If I can do a little to incite people to observe and study nature in its wondrous insect forms, and especially to interest children in such study, I shall feel that I have done a good work. In this article I propose to kill three birds with one stone: I shall describe one of our most common and interesting families of predaceous insects, the tiger beetles. I shall, by means of excellent figures, make it plain just what a beetle is; so that no reader need ever again confuse them with bugs, which I have recently described in GLEANINGS, with admirable illustrations. I shall also present a picture of insect structure which must awaken the interest of all, and prove that the bee, wonderful as it is, does not monopolize structurally all the marvels of the insect-world.

The tiger beetles are those sprightly wide-awake forms resplendent with hues of drab, white, and green, that shine with a metallic luster, which are so often seen in the bright sunshine of midday, springing up before us as we walk in the path or meadow, pushing on to alight again a few feet in advance of us. The one here shown (Fig. 1) is our most common one, *Cicindela vulgaris*. It is a beautiful dark beetle, almost slate color, with a purple reflection, marked as shown, by graceful curves of

TIGER BEETLE, MAGNIFIED TWICE.

rich cream. Below it shines with green and purple. Indeed, in grace of form, agility of movement, and beauty of coloration, it is hard to find anything in nature more interesting than some of these tiger beetles. These beetles illustrate very strikingly the curious law of mimicry. Those that rest on the sand, eagerly wait-

ing for their prey, are drab, slate-colored, or purple, and thus by their color alone are concealed from their victims; as the weasel in his winter robes of white, or the arctic fox, is hid by the snow on which it treads. Others of these tiger beetles rest in the grass, and are brilliant green, so no eye can detect them till they dart away. This adaptation through color is exceedingly interesting, and far too common to be mere accident. The walking-sticks which I described recently are green when young, and rest on leaves. As they become mature they are gray or brown, and rest on twigs, and so in both cases are protected by their color. Nor does this law cease with the lower animals. The modest retiring girl is as surely protected by her neat and unpretentious apparel.

MOUTH PARTS OF TIGER BEETLE, MUCH MAGNIFIED (FIG. 2).

The grub of the tiger beetle lives in a hole in the ground. It has terrible jaws, and rests just at the surface, ready to dodge down at the beck of danger, or to seize its prey as some unwary insect strolls across its burrow. By very carefully approaching one of these holes we can get a good view of these terrors among insects. The least noise, and they drop down quite out of sight. If we then put a straw in the hole they soon push it out as they again crowd up to the mouth of their dens.

The beetles (Fig. 1) are also fierce and savage, and so the name "tiger beetles." They are well fitted to capture and tear in pieces even the largest insects. Let us take a peep into their mouths and see how well they are armed for their work.

We count that man the biggest who does the most and acts the best; hence to measure a man we place our mental tape-line on his brain and heart. These predaceous beetles are to conquer, kill, and eat. Their mouth parts are their weapons; their legs their armor. Like the ground-beetles, we see they have an armor—their long legs (Fig. 1), which deserves admiration. Their legs are also aided by powerful wings. Let us now examine their weapons. Though we may not look a gift horse in the mouth, it is all right to gratify any such curiosity in case of a dead tiger beetle.

I do not know that tiger beetles ever kiss, or speak guile; but I am sure that they have lips that might do both were "they made that way." We

admire lips of cherry red. The tiger beetle has one of finest white. The upper lip (Fig. 2, L) is called the labrum. Notice its white color, and the three points in front. Those points would hardly be the thing if kissing were in vogue among tiger beetles. I suppose this upper lip serves as does our own, to keep the food in the mouth.

We next note the terrible jaws (Fig. 2, J). There are two, sharp, and armed with cruel teeth, and moved with tremendous muscles. Observe that these, like the jaws of all insects, move sidewise. We call these the mandibles. These are to catch and crush their victims; and the tiger itself is not better armed for such work. Alack the day for the poor caterpillar, when it and these jaws attempt to occupy the same space at the same time! But this is not all: Our tiger beetle, like other insects, has a second pair of jaws—the maxillæ. These are more slender, but far more complex and nimble than are the mandibles. Just note how they are armed with points as sharp as needles. I imagine that, while the jaws hold the insect-victim, these second jaws play back and forth like a trip-hammer, piercing the body as by scores of sharp needles, and literally making hash of it. The base, or hinge joint, of this, C, is the cardo; next comes the stipes, S, and then the three lobes from within the locinia, L; the galea, G, and the maxillary palpus, M P. The piece at the base of the palpus, P, is the palpifer. But, why so many parts? May they not be the hands that do the stirring and turning in this wondrous hash-mill or sausage-cutter? But, why does not the food fall out while it is thus twisted and turned? Below is the under lip—the labium. This is just opposite the upper lip, but is thrown forward in the drawing so as to show. This labium has a base, sub-mentum, S M, and two jointed pieces, L P, the labial palpi. Note the three spines which, like sled-stakes, would tend to retain an overload. The labial palpi, like two fingers, may aid to retain the food or to move it about. Thus we see what a marvelous structure this mouth is. How different from that of a bug, which is only a sucking-tube! The beetle, then, is higher than the bug, as shown by its more complicated structure, just as the bee, the wasp, and the ant, are higher than both. We see that the form of the beetle is also peculiar, and not easy to mistake.

These exquisite drawings were made under my direction by one of my students, Mr. A. B. Cordly. Agricultural College, Mich. A. J. Cook.

NOTES FROM THE SHARON APIARY, SYRIA.

FRIEND BALDENSPERGER TELLS US MORE ABOUT THE ORANGE-BLOSSOM HONEY, AND SEVERAL OTHER THINGS.

MR. ROOT:—I always read GLEANINGS with interest—of course, what is good and applicable for ourselves. I never followed the section question very closely, because in our place it is of no great avail. We never tried exporting sections, fearing the great danger of having every thing arrive in a muss after 10 days tossing about by the sailors, who are not good hands to handle such goods. No heed is taken of "This Side Up, with Care," etc., on tops of boxes. We therefore hold fast to the extractor, and extract as often and as much as possible. This year was nothing in the line of extracting. After a dry win-

ter, the orange-blossoms failed, almost; we then had a still drier summer, full of east winds, which dried up every suggestion of dampness, both in the ground and in the flowers. In Europe they all complained of rain, rain, rain, while we here must call it sun, sun, sun.

COLONIES TO THE SQUARE MILE.

Much has been said in GLEANINGS as to the number of hives per square mile. When I read the article of Mr. E. France, in Jan. 1st GLEANINGS, I was rather discouraged, for we had 68 hives on one spot, and our range is only the Jaffa gardens, containing very nearly 500,000 orange-trees, it is true; but then, such a number of hives located all on the same spot! I thought the bees might all visit the next gardens, and thus lose time. Now, this is a problem which some more experienced bee-keeper might answer: "Do bees of the same hive visit the same tree or the same row of trees? Do they fly in one direction?" I am inclined to think so. In 1882 I had a hive of bees which propolized the combs all over with a brown gummy propolis which they gathered from a peach-tree, not very far off; the other hives had none at all. But as to gathering honey, I can't tell of any experience, as it is always a difficult task to follow bees of one hive, unless you use the "strewing meal" system, which I never tried, except in a few cases of robbing. Do you think that bees of a hive, finding a party busily at work on a group of trees, will continue to hunt for some unexplored ones, and then keep going to that place, owning it by the right of having been the first to take possession?

Now, very likely we have not the best locality for bees, neither could we put our hives anywhere else, as only here orange-groves are to be found, and thus we could not distribute them as you would to different basswood ranges, but must keep them all here. We could divide the number of hives, and set each apiary in an opposite direction. The bees would not interfere; but, unfortunately, this year failed, so I can not find out, and must try again another year.

Going through the gardens in former years, we very seldom saw a bee here and there lost among the millions of white flowers, and we always take it as a good "omen" where we find very few bees, for then we conclude the secretion is abundant, and no reason for bees to overcrowd.

In the mountains, again, it is different. Agricultural progress restrains our fields of operation, as we depend on wild thyme, growing on uncultivated land; and as the nomadic Arabs living in the Judean wilderness advance, thyme goes back, and then the question arises, How many hives to a square mile in such a locality? for a place crowded with orange-trees certainly is far superior, and can support a greater number of colonies of bees than the same extent covered with thyme. When going over the fields I noticed great numbers of bees on the same shrub, and at once concluded that it was either a failure altogether, or too many hives were on the same spot. When I say "going over the fields," I ought to say scrambling up and down the rocks of the steep and barren-looking mountains of Judea. It is only lack of earth that has not turned all into cultivated terraces. Centuries have passed over these uncultivated slopes, and the heavy rains have carried all loose earth down the valleys. The increase of inhabitants at Jerusalem and Bethlehem has demanded a great deal of lime and wood. The

lime-kilns are a great destruction to the forests, if such they may be called. Although strict orders from Constantinople have forbidden the cutting-up of trees and roots, still the work of destruction is going on, and before long it will be difficult to find the traces of where once stood oaks, pines, carobs, or terebinth-trees. The shrubs also are disappearing; and if no stricter measures are taken by the actual government, it will be the task of the future conqueror of Palestine to restore it to what it might have looked like in the times of the kings of Israel, and then under the Romans; later, under the Crusaders; thus bee-keeping will suffer by the carelessness of the authorities as well as the communities that help the authorities in the line of completing the destruction.

PAINTING HIVES.

The subject of painting hives interested me. Our hives were painted, some red, others white, others blue; and placing the same colors in a row it had a good effect, and young queens easily found their way by marking the one they left. Surely bees see the color; for, taking away a hive, the bees coming home fly to the next hive having the same color as the one taken away, no matter if another hive of a different color be nearer the place where the removed hive stood. By migrating, the hives being placed beside and upon each other, and rubbed all the night through by the tossing movements of the camels, a good deal of paint is rubbed off, so that two seasons, or hardly three, is all our hives can bear. They must be repainted for outside comfort; and, besides, we are of the opinion the sun warps up unpainted hives. The light colors are the best, and bees feel more comfortable in them. The 10,000 hives on page 141, and 10,000 dogs, 142, that ended with the *tracks* of a dog only, I compared with our difficulties with the Turkish government—a land of “baksheesh” (gratification), where every thing can be done provided you “smear the hands,” as we put it. A few years ago the tax-gatherer, finding our “improved hives” got more honey than the clay pipes, pretended to tax our hives ten times the value of the native hive, and would hear no explanation whatever till the question was solved by the usual method, and only the tracks of his enormous demands were left. This year new difficulties arise. It seems as if the Turks were taking advantage of the continual war preparations in Europe to take us to task. Of course, when matters get too serious we are backed by our consul.

QUESTION NO. 39, MARCH 1.

Honey gets a better taste after some weeks. The orange and thyme flavors are more pronounced; but I am astonished that none of those eminent bee-keepers can tell us any thing about the wax-moth, in trying to keep comb honey from one year to another. Does sulphuring the combs not injure the flavor? With us, no combs could be kept without occasionally sulphuring; or are you not troubled with this pest? I should want P. Benson's worm annihilator to keep them off (page 258). Egyptian bees have been known and handled by very few. Although they have a bad name, we can not strictly rely on such experiences, as no modern apiarist ever tried to raise good-natured ones, or, so to say, weed out the furious ones. Cyprians, claimed by Mr. F. Benton to be the best-natured bees, have received the greatest attention, notably by himself; still they have led Mr. Abbott, in the *British Bee Journal*, to say, “I had time only to put the quilt

on.” Now, all Eastern bees are very irritable and difficult to handle, at times; but are we not living in a time when people are trying to overcome all difficulties, and especially using our senses as to what method we had better resort to, to obtain the result we are aiming at? for since we don't keep a certain race of bees as a hobby, but as profit, why not wear gloves, if such be necessary, to provide against the unpleasant infliction of too many wounds, if the Oriental races be acknowledged as superior, both as honey-gatherers and as being more prolific? The man who was cornered, page 294, April 15, about having seen comb manufactured, reminded me of a German here who would call our nice granulated white orange honey “sugar syrup,” because he heard we fed the bees sugar at times, and concluded the grains of sugar were still visible in the syrup. We are glad at times to sell off our honey at a reasonable price, and have hardly any time and would have no sale for adulterated honey; besides, we have to explain over and over again to such unbelievers, and often to no apparent avail.

I am of the opinion that bees know the place exactly where the hive stands; for on a flat plat of ground, with no trees, and very often no grass or flowers, bees still take exactly the direction of their entrance-holes, and do just exactly as the bee in Dr. C. C. Miller's apiary does—“goes back and tries again, if its bearings were not right.” Our hives are placed differently, according to the plain or mountain. In the plain, the hexagonal system is adopted, the hives being about seven feet apart from each other (2 meters); if space enough, they are set at three meters, about 10 feet, apart; and, as already remarked above, bees fly to the hive of the same color standing next to the hive taken away. I will not stand up to say bees can count, but they very likely put into their memory before leaving the apiary, especially when it is the first time, “Well, I dwell in second, third, or fourth hive, in the first diagonal white row.” Now, I hardly ever think a bee misses its house and street for its neighbor's. Moving the hives in June, I went to an olive-grove 10 miles from here, and there placed the hives round about the trees, working west before noon and east after noon, thus having shade almost all the time; and to work in the sun with the thermometer marking 95 and 122° F. is fearful, yet it must be done. I like to see a well-ordered apiary, rather than letting them stand about in every direction; but I think we can easily correct both, as two trees planted in the same line, and in the same soil, under the same care, will still grow up to look somewhat different; and to the bees' small eyes, no matter how tiny the difference may appear, they'll be sure to make it out and find their sure way.

BEE-STING REMEDIES.

Page 499 tells us about a bee-sting remedy. Oil always did good to wounds, as we read in the parable of the good Samaritan, who put oil on the wounds. It was very surely olive oil that was meant. Now, the greater part of bee-keepers find need of it; and, being stung, occasionally the poison gets inoculated into the whole system, making the body at least swell. Saliva is the surest remedy with me, and it is always carried about by everybody; but very likely it depends on whether the part stung is very fleshy or not; for then the swelling dissipates, whilst in a bony region the swelling is better seen. The pain differs according to time

of day, whether stormy, place where stung, and, particularly, the temper of the bee. Having had many hornets to kill this year, I was slightly stung by one on the arm near the pulse. It was very painful, and swollen. I thought I was swell-proof; but I had to apply some spirits of camphor to the wound. Will Professor Cook kindly tell us in what proportion the different formic-acid-possessing insects are to each other, and whether scorpions and myriapods have the same principle of poison. We often find them here under hives. The sting of a scorpion is very severe. By a sting I got in the thumb, the pain traveled all along the arm, and seemed to settle all round the shoulder and side of the breast where I got the sting; and on one occasion, I was bitten by a myriapod (forty feet) on the shoulder, through the woolen shirt. I suffered from both about three days.

PH. S. BALDENSPERGER.

Sharon Apiary, Jaffa, Syria, Nov. 7, 1888.

Friend B., we are much obliged for your very full report. It seems a little singular that you should get honey from orange-blossoms in Jaffa, while in California they furnish little honey or none at all. Very likely the peculiar circumstances of the country have much to do with it. I am inclined to agree with you, that the bees from one hive do, as a rule, work on some particular tree, or in some particular locality; but I am not satisfied as to just how they manage to follow or keep track of the inmates of their own hive. Under such circumstances as you mention, it probably is well to keep 500 or more hives in one location. I have changed my mind considerably since I saw the large apiaries of California, and heard of the large yields; but I still think there are few localities outside of California where apiaries of more than 100 hives can be kept profitably in one place. The mountain thyme that you mention is probably a good deal like the mountain sage of California.—As you state it, there seems to be a positive advantage in painting hives different colors. Any kind of dark color, however, is objectionable in our locality, because it absorbs the rays of the sun, and becomes so much hotter than a hive painted white.—Surely you can get relief from the unreasonable taxation you mention, can you not? Our proof-reader suggests that it is only the same thing over that happened in the time recorded in the Scriptures. When Christ came on earth he found just such extortion in the collection of taxes as you mention; and, dear friend, is it not true now as it was then, that there is no permanent complete remedy except the spreading of the gospel in the hearts of men?—The oriental races of bees are not acknowledged with us to be superior as honey-gatherers. They are, however, acknowledged to be more prolific. Are we to understand that you get honey from olives also? In California I saw vast orchards of olives.—It seems, friend B., you still have faith that spirits of camphor helped the hornet-stings. It is so natural to go for the camphor-bottle, that a great many of us, perhaps through the force of habit, feel better when we see the bottle in some friendly hand, accompanied by friendly words of sympathy, and the refreshing and

perhaps reviving aromatic smell of the camphor.—So you were actually bitten by a thousand-legged worm, were you? It is true, you mention that it had only *forty* legs instead of a thousand; but the fact that you suffered from its bite several days rather, upsets some of Prof. Cook's statements. Will the professor please explain?

THE SEASON OF 1888.

SELLING HONEY; SOMETHING ABOUT COMMISSION MEN.

AS I'll have to tell it any way, I may just as well say right now that the failure of our honey crops in the two last seasons has taken about the last bit of enthusiasm out of me. The season of 1887 was poor, but 1888 was a total failure, so far as getting surplus honey goes. I have 100 colonies, all in good shape to date.

They have been having good fights for the last three days. Their winter stores consist almost entirely of honey that is as black as ink. I am satisfied that, should they be confined to their hives for a period of six weeks or two months by cold weather, there will not be a bee left to tell the story.

After two weeks of bad weather during this month, there came a warm day when the bees flew out, and the hives were spotted with dark excrement, worse than I have ever seen after a long winter's confinement. It might be urged that this poor honey should have been taken away, and, instead, sugar syrup given. As an excuse for this palpable negligence, I will say that here our main reliance for honey is clover, and this has been almost annihilated by the summer drouths of this and last season, which made the prospects for a year or more ahead unfavorable. In our judgment, we should not be justified in going to much trouble and expense to save the bees. If a few days occur through the winter, offering opportunities for cleansing flights, our bees will come out all right; but if they all die I shall not feel so badly after all, as I console myself with the fact that I can purchase honey from the commission dealers for about the same money that it costs to produce it in our locality.

Why can we buy honey from commission houses for less money than it can be had of the producer? This question I put for the sole purpose of opening the eyes of bee-keepers of a certain class. For the first time, this fall I have handled a good deal of honey on commission. You see, I am getting somewhat into the commission harness; and this being the case you will bear with me if I say some plain things about dealers. Although I had not a pound of honey this year, I have been selling more this season than ever before, a greater part of it being purchased from dealers, and some I have handled on commission. At the beginning of the season for selling honey I wrote to perhaps one hundred bee-keepers for prices of honey; but as their prices seemed too high, I began to look to dealers in honey to supply me, which was done at very satisfactory prices.

"How can this be?" you ask. I will tell you just how this is done. It is one thing to produce honey; but to sell to the advantage of the producer is another and quite a different thing. Now, it is surprising how many successful honey-producers we

have; but how few who can dispose of their crop to the best advantage! Those who produce good crops, and fail to sell in their own markets, or have no home demand, ship to city markets, and employ dealers to handle their honey. Once out of their hands, they are at the mercy (?) of their commission dealer, and this explains why I can buy honey from dealers for less money than I am asked by the producer. Do you hear?

I have bought tons of honey this season from commission men, at low prices, and have made more money handling it than I would have made had my own bees produced a good crop. Hence you will see that it is not in my own interest that I write as I do about this matter.

I nearly double my money on the honey which some of you bee-keepers produce, and that, too, after commissions, cost of packages, freights, and numerous other expenses have been taken out—out of your pockets. How do I succeed in selling such quantities of honey at such good prices, you ask?

Looking at the manuscript for the above, I am reminded that I have even now exceeded the limit of space the editor will feel like according me; but I will say, if it is the desire of GLEANINGS that I shall write another article in the near future, on the subject, "How to sell honey," I flatter myself that my successful career "along this line," as Doolittle would say, would be beneficial to many who sell honey at a price incommensurable with the cost of production.

J. A. BUCHANAN.

Holliday's Cove, W. Va., Dec. 27, 1888.

Friend B., you have struck on a very important point, and we shall be very glad indeed to have you continue the subject. If I understand you, however, the reason why you are enabled to get honey at these low prices is because of the shiftless way in which many send their honey to commission men. Now, *we* are not in the commission business; but a good many bee-keepers do send us honey, and beeswax also, without telling us how much they sent; and, in fact, a good many times I do not believe they knew themselves. Sometimes they send it in, and do not say any thing at all. Most of the time we have stray boxes of wax waiting until somebody writes about them. Well, my advice would be this: Don't any of you send any honey at all to a commission man, nor to anybody else, without first writing to him, and asking him to tell you, as soon as he can, about what he thinks it would bring, giving a description of it. Better still, send him a fair sample of the lot, and let him tell you about what it will probably realize. Then when the honey is sent, tell him exactly how low he can go, and give positive directions not to sell cheaper. If he finds that he can not sell it at the price you put on it, he will advise you and you can decide to come down a little if you choose. If he writes back to you that the honey was received in bad condition—broken and leaking—if the quantity is considerable, and you are not too far away, it will pay you to go and take care of it. Fix it up, and peddle out the smashed honey yourself. You will probably make better wages at it than you can at any thing else. By so doing you will have a better opinion of commis-

sion men generally, and I am inclined to think they will have a better opinion of us as bee-keepers.

THIRD LETTER ABOUT MRS. LUCINDA HARRISON.

HER HOME LIFE, ETC.

I STARTED out to write these letters about Mrs. L. Harrison, because every bee-keeper knows her and would like to hear about her; but in reading them over, it seems that I have been writing all the time about Mrs. Chaddock, and that Mrs. Harrison comes in only *incidentally*. There are too many big *I's* in them.

I think all the bee-keepers' wives who read Mrs. Harrison's letters wonder if she is a good house-keeper, and sews on buttons and things, just like other folks. Well, she is, and she does. She has a small house, and it is as clean as a new pin, and is *always* just so. She hires a woman to come once a week and sweep her house all over. She gets rusk (a kind of light biscuit with a faint trace of sugar in them) at the bakery; she hires her washing done; and, of course, she has no milk to care for, nor churning to do, as farmers' wives have. She hires most of her sewing done, and her house-cleaning—in the spring and fall. She puts in her time cooking, washing dishes, writing for the press, working with the bees, running the lawn-mower, going to Sunday-school conventions, old-settlers' meetings and bee-conventions, and she is the most jolly woman that I ever met. Some people have *qualms of conscience*. Mrs. Harrison has none; and her cheerfulness and light-heartedness are contagious. I want to hold her up as a beautiful example for *all wives* to follow.

MRS. HARRISON AT A SUNDAY-SCHOOL CONVENTION.

When her husband came home the first night I was there, she ran to meet him. She had not seen him for a week; then she introduced me. Mrs. Harrison does not scold—not a bit—but just laughs. If the stove smokes, she laughs; if her husband gets in a hurry for the breakfast, she laughs. All the things that most women are put out about, she only laughs at; and if there is any one thing that impressed me more than another in Mrs. Harrison's daily walk and conversation, it was her *great cheer*

fulness. It is easy enough for well people to be cheerful; but when a woman is not well, it must require some effort to be cheerful. After this, whenever I get the blues so badly that I think I am going to die, I shall leave, and go and stay two weeks with Mrs. Harrison. She has a motherly sort of way of talking to me that does me good. She is a splendid cook, and all her knickknacks taste good. She broils her beefsteak, and it is juicy and sweet. She cooks apple sauce to perfection; and her tea and coffee are unexcelled. She uses a bright-red table-cloth and fringed napkins.

Her bees are in the dooryard—some of them close up against the house (when I was there; I suppose they are in the cellar now), and the hives are close together—not more than four inches apart, I think, and are painted some indifferent color.

"SHE PLANS HER WORK BEFOREHAND."

Mrs. H. has a large dooryard, filled partly with fruit-trees and grapevines; the grass is kept short all the time, with the lawn-mower, and they have walks to go everywhere. Mrs. H. is a great manager. She plans all her work beforehand, and thus saves time and strength. Her home is plainly furnished—about like the well-to-do farmers who live about here, and they have no fancy dishes on their table. They have several farms out of town, and the money comes rolling in; but what are they going to do with it? I can not imagine. I know what I'd do with a part of it, if I were in Mrs. Harrison's place. I'd have a good big house built, and have it warmed with steam, with a bath-room where folks could swim, etc.

Well, well! Mrs. Harrison is a beautiful character; and the very next novel I write I shall put her in. I think I shall have her figure in the "Cheerful Mother-in-law," because mothers-in-law have been slandered, and called cross and hateful, from time immemorial.

MAHALA B. CHADDOCK.

Vermont, Ill.

My good friend, we are exceedingly obliged to you for this home glimpse of Mrs. Harrison. Some of us might be afraid to have you pay us a visit, if you are going to write us up in that fashion. I am afraid we should not enable you to make so good a record. In regard to building a good big house, take Mrs. Root's advice, and—don't! We manage a good deal as Mrs. Harrison does, about sweeping and washing; but we have decided that a larger house than one needs, is a misfortune. Mrs. Root even now longs occasionally for our old little home, or

for one like it, such as Ernest and Maud have across the street. Fathers-in-law and mothers-in-law are excellent things to have, just a little way off—say across the street. A house large enough to have several families under one roof is good in theory, like tenement bee-hives; but I believe that most of those who were so enthusiastic about tenement hives have come back in favor of each colony in a hive by itself. "Every tub on its own bottom," you know.

BEES AND NEIGHBORS.

NOT BEE-LEGISLATION, BUT EXCLUSIVE RIGHT OF TERRITORY BY PURCHASE.

THE only fair and just way for a man to get the monopoly of the bee-business in any locality is for him to pay each farmer or lot-holder within the flight of his bees a certain sum yearly, not to keep any bees on his property. If a law could be had, selling rights to any one person to keep bees in a given locality, then only the rich or well-established apiarist could secure the rights. The poor widow or cripple or broken-down professional man would not dare to keep bees within a certain limit, because the Honorable Mr. Moneybags had bought the local right for a few paltry dollars. Lazarus could not keep bees within three or four miles of Dives' residence. The poor widow could not earn a mite for the Lord's treasury by keeping bees, because some Pharisee had bought the township-right.

Any law giving one person advantage over another is wrong. According to the plan at the beginning of this article, the widow wishing to keep bees need not sell her right, and the law would not take away her right. Any person should have the right to keep a few bees, or as many bees as he chooses, provided his bees do not harm his neighbors or passers-by, and are not a nuisance.

Just here I should like to say, no man has a right to keep bees in a town if his bees *really* annoy his neighbors. By annoy, I do not mean make nervous people fidgety. No one has a right to keep chickens to scratch his neighbor's garden; neither has he a right to keep bees where they will sting his neighbor's children. Bees are bees, and bees will sting. Whenever my bees become a nuisance I will move them out of town. Our neighbors have rights as well as ourselves.

The same principle applies to foul brood. That disease should not be treated with anything except the furnace. It should be burned, destroyed, root and branch, upon its first appearance. We owe this to our neighbors as well as to ourselves. "Do unto others as you would have them do unto you." You would not like to have a neighbor tolerating and treating foul brood within the flight of your bees.

Last spring I selected two colonies, about equal in queens, strength, and in good condition. Over one I used a slatted honey-board and a T super. Over the other I used half-depth wide frames, with no honey-board. The one under the T super swarmed out without touching the sections. The one under the half-depth wide frames stored me fifty or sixty sections of surplus comb honey. The honey-boards seem to remove the surplus boxes too far from the brood-nest in a poor season, when honey is scarce and comes in slowly. I think the

bee-space between half-depth wide frames should be $\frac{1}{2}$, the same as the sections, thus leaving no little line along the edge, to be propolized.

Once this summer my bees started booming on something. I could smell the honey ten feet or more from the hive. I supposed it was red clover. Upon investigation I found no bees on the red clover, but found the common burdock in bloom, crowded, roaring with bees.

I fixed my bees for winter November 3, and wore my overcoat while doing so. I believe they have had only one day's good fly since then.

PHILO S. DILWORTH.

Pittsburg, Pa., Dec. 19, 1888.

Friend D., your point is a good one. Go to your neighbors all round about you, if you are located in the country, and get them to sign a paper, agreeing not to keep bees under a certain number of years. If they have no notion of keeping bees any way, the greater part of them will be glad to assist you by signing the paper, without pay. Those who keep bees already, and especially if they are not doing much with them, will perhaps sell out reasonably, and, for a small sum per year, give you the sole privilege. You could easily make a canvass of your vicinity—say covering the land within two miles of you in each direction, to see what it will cost you. If too expensive, don't go into it; but I think that many of the friends could easily in this way secure the right to keep bees, without any unpleasantness or unfriendliness. Where real estate is transferred to a party, I suppose a paper could be drawn up, making the same regulation hold, even after the transfer. If your bees boomed on *burdock*, it seems to me it is something of a reflection on the farmers in your locality.

BEEES AND CANNING-FACTORIES.

A BEE-KEEPER OBLIGED TO GO OUT OF THE BUSINESS.

I RECEIVED the last number of GLEANINGS a few days ago, and I am sorry to say that this must be really the last number I shall get of my most favorite journal, as I shall be out of the bee-keeping business by next spring, and, of course, shall have no further use for a bee-paper. The business of keeping bees, at least around here, is (to use a common expression) about played out. The last two seasons were very poor indeed. Last summer I got absolutely nothing from my 80 swarms; and when there is a good season (as we had two years ago) I have to sell the very best of white comb honey in pound boxes for 10 cts. a pound. That is for less than I can afford to raise it. But in spite of these discouraging prospects I should have kept on, hoping for better times in future, if I had been left undisturbed by outsiders, and if a certain institution that has sprung up in my neighborhood had been built somewhere else. The institution I have reference to is a factory for canning fruit, that was built last spring, a few rods from my home, and that turned out to be the ruin of my bees. As soon as business was started up (canning pine-apples in June), my bees went there in perfect swarms, to be drowned in sugar syrups, or to be killed in some way; and in a little while my best colonies were so depopulated as to

be perfectly useless. To prevent my bees from getting into the building by putting wire cloth before doors and windows was not possible, as part of the rear of the main building, where they unload fruit, is all open, and I had to try the next best thing I knew of; viz., to shut them up in their hives. I hurriedly made frames, covered them with wire cloth, put those on top of the brood-frames, shut the entrance-holes with wire cloth, allowed the bees to fly about an hour before sunset, and shut them up again late in the evening; but in spite of all this trouble I could not save them, for great quantities of them worried themselves to death in the hives, and it proved just about as disastrous to them as to allow them to go and meet their fate in the factory. Although the proprietors of the factory behaved to me like gentlemen, at least this last season, there is no way of telling how they might act if this nuisance should keep on; and it was indeed a great nuisance to them, as I saw myself.

Aside from having my bees ruined every summer, I run the risk of being involved in a lawsuit by and by; and as the canning-factory, to judge from the large and substantial buildings erected for the purpose, seems to be a permanent affair, there is only one way left to me—give up keeping bees in the future. I know I shall feel dreadfully lonely without the dear little creatures; but I have to submit to it.

CHAS. KLIMITZ.

Batavia, Genesee Co., N. Y., Dec. 21, 1888.

Why, good friend K., why should you abandon bees, because your locality seems to be just now a bad place for them? Dozens of the friends in California, have been in the same predicament; but instead of abandoning the bees they simply moved them to a locality where they did not annoy anybody else, and usually they have succeeded in getting a place where enough more honey can be secured to cover all the expense of having an apiary away from home. During the honey season, where the yield is good you can arrange to have a sort of summer residence with your bees. Then you will be right in fashion. You can shut up the house during the hot weather; and instead of going to the seaside, or to some popular resort, you can go and live with your bees and get good pay. I would much rather move the bees to some other locality than to try fastening them up in their hives. I am inclined to think the latter course will always turn out about as it has with you.

SECURING COMB HONEY.

MILLER VERSUS DOOLITTLE ON THE MATTER.

AS I am very much interested in the discussion now going on between friends Doolittle and Miller, I thought I would put in a word in favor of them both. The subject they are discussing is not exhausted, by any means, but is, in fact, one of the most interesting that has occupied the pages of GLEANINGS for a long time. As to the real point at issue between two old and experienced bee-keepers like Miller and Doolittle, there will not be much left to quarrel about, I think, when they fully understand each other's positions. There is so much to be taken into consideration, that neither the tying-up plan nor Mr.

D.'s side and top storing plan will succeed under all conditions. Now, whatever works satisfactorily in a country where the honey-flow comes at an unnatural time of the year, as it does in Cuba, when the bee-keeper has got to work every way he can think of to get his bees in condition to take advantage of the early flow, that way is the best. Then comes in Mr. Doolittle's plan; i. e., have your bees when the honey-flow comes. But will the tiering-up plan work in the case of a long honey-flow? No, for you will not get the best results in that way, for too much time is wasted in capping the honey; too much heat is wasted by adding more room. Now, there is where friend Doolittle is right, according to my experience—keep the bees compact and warm; for never, in my experience of five years in Cuba, did I find that I had my bees too warm. We always had them snugly tucked up under enamel cloths, and in tight hives. How far you can carry the expansive plan of managing bees for surplus, is a point that can be decided by circumstances only. Just what those circumstances are at all times, I would rather some one else would tell than I. My experience with colonies in managing them for extracted honey is to keep them warm; give no more room than they can occupy, and have *nothing* between the brood and store combs; nothing to hinder the free passage of heat from the brood-chamber to the surplus department, *right directly over the brood*. But in case a colony is not strong enough to occupy two stories, very good results can be secured by confining them to the brood-chamber, and working them on the side-storing plan.

What Mr. Doolittle says about the dry-goods box, I can hardly agree with; that is, if we take a dollar-and-cents view of it. Let friend Doolittle, next spring, take 1 lb. of bees and put them in a dry-goods box; then put the same amount of bees in a hive with a division-board all tucked up warm, and report results in the fall. I contend that more honey can be secured by keeping the bees crowded and warm than by giving them lots of room and compelling them to store what they can in old dilapidated hives. Now, how many bee-keepers do you think judge correctly of the proper condition of their bees when they open a hive? I fear too many think their bees need more room when they are in just the right condition to do the best work. A friend said to me last summer, "Aren't you afraid your bees will swarm?" I said, "No. If they want to swarm, I let them do as they like, but seldom more than once, and that does very little if any harm." As I said at the beginning, I want to see this subject properly discussed: "The giving of more room when the bees do not need it."

San Diego, Cal., Dec. 13, 1888.

A. W. OSBURN.

THE CORRUGATED HIVE-COVERS.

FRIEND REESE REVIEWS THE MATTER.

I WAS so thoroughly imbued with the idea that I had hit on the best water-proof hive-cover, and only positive relief from swelling from bee-stings, that your comments on page 766 were more than a surprise to me—especially when you object to the weight of the corrugated iron. Let us review the matter a little, and see if there is not more merit than you have discovered. One square foot of standard corrugated iron, painted,

weighs $\frac{7}{16}$ of a pound, or a little less than $\frac{1}{4}$ of one pound. A piece 18 inches wide and 24 inches long, which would cover a Simplicity hive nicely, projecting over each side about one inch, and far enough over the front to protect the entrance from much rain, snow, or hot sun, would weigh just $2\frac{1}{16}$ pounds, and cost just 12 cents, all painted and ready for use. Now, when you take into consideration the fact that no other cover, is really needed, it is not so expensive or heavy after all. I put the sheet of corrugated iron right down on the enamel cloth that covers the sections or frames, and lay any old boards on top as a protection from the hot sun, and to keep the iron in place. When winter comes we will take it for granted we use Simplicity hives, just set an empty brood-chamber over each colony. Over the frames put a piece of old carpet or a felt or straw mat; on this, in turn, put four to six inches of planer shavings or sawdust, or a chaff cushion, and over the whole the corrugated iron cover. This will admit sufficient circulation, and we may rest easy so far as protection is concerned. For a chaff hive which must be kept dry, well, you can see how it is yourself. If you will turn to page 15 of Dr. Miller's "A Year Among the Bees," you will see his "tolerably light cover" weighs $5\frac{1}{4}$ pounds, and costs from 20 to 25 cents. How does the comparison strike you?

I now prefer the $\frac{3}{8}$ -inch corrugations, and send you herewith a sample with the maker's name. It would be quite a job for the majority of people who keep bees, to fit tin to their old leaky covers, tack it on and paint it.

The bee-sting remedy, you will please understand, is simply to make a slight cut, merely passing through the skin, just where the bee-sting entered, and allowing the alkali to come in direct contact with the poison, causing neutralization at once, and the swelling does not take place. The incision made with the knife can scarcely be noticed a few hours after, and is not painful, as the flesh is not "dug into" as you term it. In a recent number of one of our bee-journals some one suggests the use of the hypodermic syringe to inject an alkali into the venomous parts, which is certainly a capital idea if we could have at hand, as convenient as our pocket-knife, the little expensive syringe. My two little boys, four and five years of age, invariably come to me when they get stung, to get the soda water put into the stung place on their bare feet, etc.; and when I am not at home when they are stung, they always swell, and regret my absence.

J. S. REESE.

Winchester, Ky., Nov. 9, 1888.

Many thanks, friend R., for the sample of your corrugated iron. It will no doubt answer splendidly; but in our locality it would be blown off by the winds, and they would get smashed and battered up, so we should be obliged absolutely to hitch them fast to something. Another thing: If anybody should sit down on a hive, or even if one hive were rested on top of another, they would be pressed out of all shape. I do not believe I should like them nailed fast to a wooden cover. In that case the tin we already use would be cheaper, and I think rather preferable, because it is smooth on top.—Cutting into the flesh with a knife, in order to get the alkali in contact with the poison, may be a positive remedy. I am

afraid, however, that I should conclude, if I tried it, that I could not see any very great difference.

HEADS OF GRAIN FROM DIFFERENT FIELDS.

WINTERING A HIVE ON A SUMMER STAND WITHOUT A BOTTOM.

WHILE I was at the convention at Albany last winter, a gentleman, I do not remember his name (he was on the platform at the left of the president), said that his hired man had a hive of bees in a box hive, standing on four posts three feet high, with no bottom in the hive, and it stood outdoors all winter, and the thermometer had been below zero several times during the winter, and that the hive of bees came out better in the spring than his own bees that he had put in his cellar, as he supposed, in the best possible shape. He was asked by some one in the convention if the hive was high enough so it did not get snowed under, to protect it from the wind. He said it was about three feet from the ground, and did not get covered with snow, but that the whole bottom of the hive was open all winter. Now, my theory is that there was no condensation, as the temperature outside and inside of the hive was nearly alike, except, perhaps, in the cluster of the bees a little warmer. I also think that there was no circulation or current of air, but instead there was a penetration of fresh air, or, in other words, the air formed an equilibrium of temperature by penetration of the free and open bottom of the hive; and when there was a change in the temperature outside, there was a corresponding change inside also. As I am only a novice in bee-keeping, I will not make any suggestions.

West Troy, N. Y.

A. E. CLUTE.

Friend C., I can not recall to mind now the name of the gentleman you mention, but perhaps some of the other members present can do so. Through the back volumes of our bee-journals we have had a good many reports such as you give; but instead of having the whole bottom of the hive open, I think the effect would be still better if they had an opening from four to six inches square. To prevent mice from getting in at this opening, it had better be covered with wire cloth; and when we get down to it, a good-sized entrance properly protected with the cloth, in such a position that it is not likely to be closed up with snow or ice, pretty nearly fills the bill. In fact, I have always favored the idea of having the bees enter the hives from under the bottom. A Simplicity hive, pushed forward on its bottom, gives us just exactly this kind of entrance. Now, after having fastened the hive so it can not slip forward on the bottom-board, tip it up as illustrated on page 25 of our last issue, and you have an opening that lets all the dead bees fall out, and gives every advantage of a hive without a bottom. If you put wire cloth over this large entrance, however, to keep out the mice, the dead bees can not fall out as they would otherwise. Some years ago the matter was pretty strongly talked up, of

having hives as tight above as they could possibly be made, and no bottom-board at all, during the winter time.

SIZE OF SECTIONS, AGAIN; M. A. KELLEY RENEWS THE MATTER WITH DR. MILLER.

Please allow me to thank Dr. Miller for his able reply concerning the "size of sections;" also to answer his question, "Why does the $4\frac{1}{4} \times 4\frac{1}{4}$ section seem to you too small?" Simply, sir, because, in ordinary seasons, it will not hold one pound. I tried to make this plain, as a careful reading of my letter will show. To call it a 1-lb. section is a misnomer, and to sell it as such is something worse. True, as you remark, no size will give uniform weight; but the variation should embrace 1 lb. between its extremes. But how is it with the so-called 1-lb. sections? With me they average from 13 to 15 oz. only. Taking 2 oz., then, as an average variation, it should be from 15 to 17 oz., thus giving some chance to strike a general average of one pound. In giving your experience with various widths, you stop short with 8 to the foot. Tell us how much your 7 to the foot and 6 to the foot or $1\frac{1}{2}$ sections weigh. Did you ever have a single super of the sections in question in which they would average 17 ounces each? Have you not had hundreds of supers of the same size of sections in which they would average not more than 15 oz. each? Doubtless your own experience will indicate the truth of my assertion, that the $4\frac{1}{4} \times 4\frac{1}{4}$ is too small. This may seem to be, but it is not, a small matter. Giving good weight maintains a good reputation, which is no small matter.

Milton, W. Va., Dec. 31, 1888.

M. A. KELLEY.

Friend K., you seem to overlook the fact that the Simplicity sections are made now of a good many different widths. I believe I put the first Simplicity sections on the market that were ever heard of. They were arranged so that eight would fill a Langstroth frame, and, as originally made, they were plump two inches. Now, without separators, and as I first used them, they average more than a pound. The same sections with separators average a trifle less than a pound; but as it is entirely out of the question—at least, so far as I know—to produce sections weighing even very nearly a pound, we always sell them by weight; and if we sell them by weight we are just about as badly off to have them run *over* as to have them run *under*. To be very exact, perhaps we should not call them "one-pound sections." Giving good weight maintains a good reputation, no doubt; but I do not believe it advisable to give very much more than a pound. Honey is sold by weight the world over, so far as I know. In California they sell apples and potatoes and coal, and almost every thing else, by weight; and I think it would be well if we should follow their example in many things.

IS HONEY VINEGAR AS GOOD FOR PICKLING AS CIDER VINEGAR?

Reading the articles in regard to honey vinegar in November and December GLEANINGS moves me to make some inquiry of the feminine portion of GLEANINGS' readers concerning it. I will first state that we have for a number of years made

considerable vinegar from waste honey, to which we added some fruit juices, as currants, grapes, etc. In making jelly I put cold water upon the pulp left after squeezing out what juice I want for the jelly; and after straining it, put it into the vinegar-barrel, together with the skimmings from the jelly. This gives a beautiful color and flavor to the vinegar, which can not be surpassed for table use; but I find that, while I can make very nice sweet fruit-pickles by using the usual amount of sugar, I can not make good vegetable pickles, even by the use of sugar. The pickles are delicious when first made, but soon the vinegar turns white, and, if neglected, a heavy coat of mold will be found on the top. I have never experienced this difficulty when cider vinegar was used, and I desire to know whether others have found the same difference between vinegar made from honey and that made from cider.

EMILY E. WEST.

Flint, Mich., Dec. 14, 1888.

My good friend, we have had considerable experience in the use of different kinds of vinegar for pickles. Yes, *sad* experience. Now, while cider vinegar will perhaps keep pickles longer than vinegar made of honey, or water sweetened with the residue from making maple sugar, etc., our experience is, that no kind of vinegar, except a high quality of white-wine vinegar, is suitable for keeping pickles any length of time. Cider vinegar does very well where the pickles are used up before warm weather comes in the spring; and *very strong* cider vinegar may keep them through the summer; but with white-wine vinegar, that costs something like 30 cts. a gallon, we can keep pickles year after year. Perhaps cider vinegar may be so treated and so concentrated as to keep pickles safely through several months of summer weather. It may be, also, that honey vinegar that is *very strong and sharp* might answer.

JAPANESE BUCKWHEAT NOT AS GOOD A YIELDER OF HONEY.

Japanese buckwheat yields three times as much as the silverhull, and it is two weeks earlier; but the bees do not work on it so well as they might if they had nothing else. I do not want to raise it for the bees.

WHITWOOD FOR HIVES.

I think that whitewood makes the best hive and the best frames. The bees like whitewood the best of any kind.

My bees have done well this summer. They have made 1700 lbs. of honey. THOMAS OBERHITNER.

Deshler, O., Dec. 3, 1888.

CAGING SURPLUS QUEENS DURING WINTER, OVER STRONG COLONIES.

Can I get a book on bee culture, from which I can learn how to save queens sure, during the winter months? I mean queens for which I have no use in the fall. If so, have the kindness to give the name of the book and the price. J. GLANZMANN.

Altus, Ark.

We might refer you to our A B C of Bee Culture; but neither that nor any other book that we know of would give you any *sure* method by which you could preserve queens alive when separated from the cluster, either by caging or otherwise. We have caged queens over a strong colony of bees

where there was already a reigning queen, perhaps one or two months during the winter. We never had any yet that survived until they could be made use of in the spring. A month or six weeks is as long as we could keep them after confining them in the manner explained.

HONEY FROM APPLE-TREES: 54 LBS. IN SEVEN DAYS, BY ONE COLONY.

Mr. Doolittle, in his review of your A B C book, says that apple is a great yielder of honey, and my experience during the past season has convinced me that he is right. I joined your A B C class of bee-keepers in May, 1887. I then bought three colonies of bees for \$18.50. I increased them to 6, and got 330 lbs. of comb honey. I wintered them without loss, by packing in chaff, 10 to 12 inches on each side of the hive, and about 18 on top. I opened them April 1st, and found that brood-rearing was well under way, but I thought they had too much honey (about 30 lbs. per colony), so I extracted the outside frames and placed them in the center of the brood-nest. I then covered them very warm, and fed the honey back to them slowly. They increased very rapidly, and I think those hives contained as many bees May 15th as they have at any time since. I had one colony which stored 54 lbs. of apple honey in seven days; another one filled 24 sections in four days, and then swarmed and made a good start in their new hive before apple-bloom was gone. I did not have a colony which stored less than 10 lbs. of apple honey in the sections. Sections of empty comb, when filled with apple honey, were sealed almost as soon as filled; and I doubt if even *you* could distinguish them from newly built combs. There was but little clover, and they worked only three days on basswood. I got 300 lbs. of comb honey, and increased my 6 colonies to 17. When September came my colonies were light, and the brood-nests were nearly empty. I fed them 300 lbs. of sugar, so I did not make very much; but I am not at all discouraged. I have gone into the business to *stay*, and I shall stay whether I succeed or not.

If you can read this, you will do well. I wrote it while lying in bed with a broken leg.

Gilead, Mich.

D. E. WEAGE.

Friend W., I have long been aware that apple-trees often produce enormous quantities of honey. There are several obstacles in the way, however, of getting such a yield as you mention. One is, the bees are seldom strong enough to take advantage of it. Quite a few times, when we happened to have powerful colonies during apple-bloom, we have had quite good yields. I feel sure, however, we can, if we choose, have at least a few rousing colonies during apple-bloom. The other trouble is, and perhaps the worst of all, that the weather is oftentimes very unfavorable for gathering honey from apple. In fact, I have known bad weather almost through the entire apple-bloom period. Then there are seasons when apple-trees do not blossom very much, and also when a profuse bloom gives little or no honey. I think it is well, however, to prepare ourselves as well as we can, especially when we are in a locality where apple-trees are plentiful. If we could find a spot protected by tall forest-trees, or, better

still, ranges of hills, something like the mountains of California, we should stand a much better chance of securing apple-bloom honey; and in locating an apiary I think I would consider well the matter of apple-bloom.

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

All queries sent in for this department should be briefly stated, and free from any possible ambiguity. The question or questions should be written upon a separate slip of paper, and marked, "For Our Question-Box."

QUESTION 100.—*a. What is the lowest temperature, Fahrenheit, that you usually experience in winter in your locality? b. How many days is the mercury below zero, Fahr.?*

a. From 18 to 30°. b. From 20 to 40.

G. M. DOOLITTLE.

a. 20 to 30 below zero. b. I do not know.

GEO. GRIMM.

a. 20 to 25; b. probably 40 days. DADANT & SON.

a. 20° below zero. b. Not over 25 on an average, I think.

JAMES A. GREEN.

Usually about 15° below, occasionally 20° below. b. From eight to ten; some winters more, some less.

P. H. ELWOOD.

a. Usually about 16 below zero. b. 10 to 20. Occasionally a winter when the mercury does not go below zero.

H. R. BOARDMAN.

15 to 18 below zero, ordinarily, but the past four winters have been severe, the mercury going as low as 28 and 30 below. b. I have kept no record.

MRS. L. HARRISON.

We have had the mercury 24° below zero during several winters, and five or six years ago the mercury was in the twenties below zero for almost two weeks.

CHAS. F. MUTH.

a. In 1872 and 1885, the coldest was 15° below zero; 1873 and 1884, 14° below; 1875, '79, '86, 12° below; 1880, '83, and '87, 10°; in 1874, '77, '78, '80, and '81, 2° below. b. Usually but one day, very seldom more than two or three.

DR. A. B. MASON.

In this locality, 42 north latitude, we consider 15 below zero as extremely cold, although we have had 30 once or twice. We frequently get through the winter with nothing more than zero, or 5 and 6 below.

JAMES HEDDON.

The lowest is about 18° above 0. As a general rule we don't have more than 20 freezing days in a winter, although I find that our winters are more sensitive than in the North, on account of the continual changes from warm to cold. I have seen the four seasons in 24 hours, and that nearly every winter.

P. L. VIALLO.

Seldom more than 16° below zero, and seldom more than two or three days at a time. My answers to the general questions are in the main from experiences gained in Central New York, where the mercury often falls to 30 below zero for a week or more at a time, at intervals during four months or more.

L. C. ROOT.

a. In my old locality in Northern Iowa, the thermometer usually goes as low as 33° to 37° sometimes during each winter. b. I can not answer this

question accurately; but one winter the thermometer was as low and lower than zero every day during the entire month of January. I think that my locality was as cold as that of any other contributor to your Query Department, and we made chaff-hive wintering as much a success as did others with their cellars.

O. O. POPPLETON.

My location is Ohio, near the Michigan line. My own weather-records cover eight winters, and show as follows:

Winter of 1880,	'1 lowest,	-16°;	below zero	14 days.
" " 1881,	" " "	5°;	" " "	None.
" " 1882,	" " "	14°;	" " "	11 days.
" " 1883,	" " "	-29°;	" " "	11 "
" " 1884,	" " "	-26°;	" " "	31 "
" " 1885,	" " "	-10°;	" " "	9 "
" " 1886,	" " "	-17°;	" " "	8 "
" " 1887,	" " "	-10°;	" " "	7 "

E. E. HASTY.

Dr. Miller gives us below some figures from the Illinois State Weather Service, the observer, Mr. J. W. James, being a neighbor of his.

The average of the lowest temperatures of the past 27 winters is 21° below zero. The lowest I have recorded here is 31° below zero, Jan. 5, 1884. The average number of days below zero, in 28 winters past, is 17. Greatest number, 38, winter of '84, '85; least number, 3, winter of '77, '78.

I have been meteorological observer here since Oct., 1860; meteorological observer to Smithsonian Institution, May, 1869, to Dec., 1873; voluntary observer of Signal Service, U. S. A., Jan., 1874, on; observer Illinois State Weather Service, 1877, on.

The above includes the three winter months, December, January, and February, only.

JOHN W. JAMES.

Dr. Miller adds :

From the above, I suppose the answer is—*a.* 21°, *b.* 17. This certainly is warmer than ordinary thermometers make (I've seen it down to 37°), but it ought to be correct.

C. C. MILLER.

My impression is, that Question *b* was not understood by all who answer. For instance, friend Hasty says there were seven days last winter when the thermometer was below zero. Now, I think he means there were seven days when the thermometer was below zero for perhaps half an hour or more. Others have evidently counted the number of days when the thermometer remained below zero for fully 24 hours; and in our locality that seldom occurs during any winter. A self-registering thermometer hangs on our porch, and the register stands now where the mercury left it last winter—just a trifle below zero. For a short time, mostly during the night, the mercury was down about zero, but I think not more than about seven times during the winter. During this present winter we have yet had no temperature lower than eight above, and that only once. Now, where these lower temperatures are of only transient duration—say an hour or two—bees or any thing else seldom suffers very much; but where we have a continuous week of weather below zero, especially if accompanied by high winds, then look out for your bees, cellars, greenhouses, cold-frames, etc. We are very much obliged indeed to friend Hasty for his accurate record. We notice that, in the winter of 1881 and '82, the lowest temperature was

five above. Friend Hasty's record would, I think, answer very well for Medina. At the present time both radishes and celery are growing in the open ground that have as yet received no injury. They are, however, protected by buildings. Now, this latter point is a very important one. In California, people have hunted up localities protected by mountains, and in some cases they are nothing more than moderate hills, and these hills furnish sufficient protection for raising all kinds of tropical plants and vegetables. In Salt Lake City we had very pleasant weather—no frost; but when the train brought us to a notch in the mountains where the northeast wind swept through, the ground was frozen wherever the wind struck; and on the northeast side of the mountains we found the ground frozen hard, and covered with snow. Are we making sufficient use of the hills we have, for protection in a similar way, for our bees and gardens?

QUESTION 101.—*What method of wintering prevails in your locality—that is, outdoor or cellar wintering?*

Both.	DADANT & SON.
Cellar.	P. H. ELWOOD.
Cellar.	A. J. COOK.
Cellar.	C. C. MILLER.
Cellar.	DR. A. B. MASON.
Outdoor.	MRS. L. HARRISON.
Outdoor, generally.	CHAS. F. MUTH.
Outdoor, generally.	L. C. ROOT.
Cellar wintering exclusively.	GEO. GRIMM.
Outdoor wintering is almost universal here.	
JAMES A. GREEN.	

The prevailing method is indoor, especially among the most advanced bee-keepers.

H. R. BOARDMAN.
Outdoor, as it is seldom that the bees are three consecutive days without flying. P. L. VIALON.

About half in cellar and half on summer stands, most apiarists using both methods during the same winter.
G. M. DOOLITTLE.

Both are commonly practiced here. During our severest winter those did best who wintered indoor; and during mild winters it was just the other way.
JAMES HEDDON.

The few old-style bee-keepers still winter outdoors mostly. Those who are up to the times, most of them, winter in cellars, I believe. As for myself, I winter mostly out of doors.
E. E. HASTY.

In my immediate locality in Iowa, chaff-hive wintering was mostly practiced, and was most successful; but a short distance away, in localities where the soil was of a different nature from what it was where I lived, cellar wintering was in most use.
O. O. POPPLETON.

I hope you will excuse me, friends, for saying, as I read over the above answers, I can not help thinking that those who answer are perhaps unconsciously prejudiced a little in favor either of cellar or outdoor, as the case may be. Friend Hasty says that, in his locality, which is about the same as ours, a few old-style bee-keepers winter out of

doors mostly; then he adds, with characteristic frankness, "Of whom I am which." Now, it is not at all unlikely that I too am prejudiced. I do not believe that, in our locality, nor in friend Hasty's either, it is profitable for the average bee-keeper to undertake to winter in the cellar. Friend Heddon gives a wise suggestion in regard to his locality. Then to get at the truth of the matter, the question arises, Which occurs oftener—mild winters or severe ones? Friend Poppleton succeeded with chaff hives, just as we do; and his report of the severity of the winters in Iowa is perhaps as bad as any who have answered. His remarks in regard to the soil refer, I presume, to its adaptability for constructing wholesome cellars. A cellar in a sandy or gravelly soil, especially if it is in a side-hill, is certainly much better than a cellar in level, wet clay soil.

QUESTION 102.—*What is your average consumption of stores per colony, as nearly as you can estimate (if you can not give exact figures), from October to May? State whether this average is for cellar or outdoor.*

25 to 30 lbs. for indoor wintering.	H. R. BOARDMAN.
For outdoor wintering, about 18 lbs.	JAMES A. GREEN.
15 to 25 lbs. I winter outdoors always.	CHAS. F. MUTH.
About 15 lbs., indoors; 25 lbs. outdoors.	L. C. ROOT.
40 pounds for out of doors; 30 pounds for cellar.	DADANT & SON.
I think about 15 to 20 pounds; cellar wintering.	GEO. GRIMM.
Between 6 and 11 pounds. I winter in the cellar.	DR. A. B. MASON.
About 10 pounds for the cellar, and 14 for those wintered outdoors.	G. M. DOOLITTLE.

18 to 20 lbs. out of doors; cellar, 9 to 10 lbs. This is estimated. I can not give exact figures.

MRS. L. HARRISON.
I judge from 12 to 14 pounds. I have never weighed. This is for cellar, and about two months outdoors.
P. H. ELWOOD.

From October 1st to April 10th, not more than 7 pounds in cellar; about twice that amount outdoors, packed or in chaff hives.
A. J. COOK.

Outdoor wintering. I think I will put it at 12 pounds, with the remark that it would take a good deal more pains in weighing, etc., that I have given to the matter, to give the figures very much scientific value.
E. E. HASTY.

For cellar, perhaps 20 lbs. The only actual figures I have are of four colonies, weighed October 21, 1881, and April 17, 1882; the losses in weight being respectively 13¼, 19¾, 21½, and 25½, or an average of 20 lbs. This, of course, included dead bees as well as stores.
C. C. MILLER.

In this State (Louisiana) we have to give the average from November to March. It takes fully 25 pounds to bring a colony to the 15th of March. The consumption doesn't seem to be much until about February 1; but after that it is very rapid, which is no doubt due to the rapid breeding.

P. L. VIALON.

I can not say exactly; but I should judge about 20 pounds. Of course, much of this was used outside of wintering proper. I wintered in chaff hives, out of doors.

O. O. POPPLETON.

I can not give you an average of the stores consumed from Oct. 31 to May 1. It requires about twice the honey to carry bees through from Oct. 31 to April 1 outdoors that it would in the cellar. During the months of April they will be outdoors in either case, usually. I think perhaps the average is 10 pounds indoors and 20 outdoors, between October 31 and April 1.

JAMES HEDDON.

There, friends, I am very glad this question has come up in the shape it has, that you may see how much we differ, or, I am tempted to say, how loose some of us are in our estimates. H. R. Boardman says from 20 to 25 pounds, and he is one of the best bee-men there are in the lot. I wish he had told us whether he just guessed at it or whether he had been in the habit of weighing. Dadant & Son are worse yet—30 pounds to the cellar, and 40 outdoors. With that great big Quinby frame of theirs, there must be such rousing colonies that it takes double, or even more, than some of the rest of us report. Now, in contrast with the above, Dr. Mason says from 6 to 11 pounds. Doctor, stand up and tell us what you mean by such a statement as that. You remind us of the man who brought home two stoves. When his wife asked what he meant, he said the agent warranted that kind of a stove to save half of the fuel; therefore with commendable good sense and forethought he bought two stoves, that he might be enabled to save the whole of it. If you can winter good colonies of bees on from 6 to 11 pounds of stores, we had better ship our bees to you, and get you to winter them for us; that is, where it takes from 30 to 40 pounds. My experience would agree pretty nearly with Doolittle's, only I should add, some rousing big colonies might need 20 pounds, and I do not know but we have had a very few in our experience that used up 25 pounds; and I also want to add, they used it profitably, for the 25 pounds of stores enabled them to send out tremendous swarms very early; or when we practiced extracting they gave enormous crops of honey, while moderate ones did nothing to speak of. Prof. Cook has also wintered bees on only 7 pounds of stores. Come to think of it, I have done even better than that. I have seen a weak colony consume only a very small amount of stores during winter; then when spring came, as they just managed to pull through, they got down to a mere handful, and did not consume any stores to speak of until honey commenced coming. Under the circumstances it cost little or nothing to winter them; but the profit during the summer from them was also little or nothing, for it took the whole season for them to build up in decent shape for winter. There, friends, you have my explanation of these reports, so widely different. Is it not a pretty good one? Another question arises—Which is the more profitable, colonies that require from 20 to 25 pounds to carry them through, or those that will get along on from 5 to 10 pounds?

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from \$1.00 to \$1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows: viz.: Sheer Off, Silver Keys, The Giant-Killer, or, The Roby Family, Rescued from Egypt, Pilgrim's Progress, and Ten Nights in a Bar-Room. We have also Our Homes, Part I, and Our Homes, Part II. Besides the above books, you may have a photograph of our old house apiary, and a photograph of our own apiary, both taken a great many years ago. In the former is a picture of Novice, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

HOW many of our young folks can draw pictures? Hold up your hands. Why, almost all of you can. But, how many can draw *real* nice ones? Let's see the hands again. Is that all? There are only just a few hands. Well, that will be enough. We want some of you who "know how" to draw, to illustrate your letters. If your papa has gotten up some new "fixin'" for the apiary that he thinks is real nice, suppose you make as good a picture as you can, and then describe it in your own words. If the tool or device shall be of value to bee-keepers at large, then we will engrave it; and how nice it will be to see your little letter with a picture beside it, that you made yourself! Remember, your drawing must represent something useful, if you expect to see it reproduced in these columns. During the last few days the juvenile letters have been coming in at a good rate, for which we extend our thanks. They are exceptionally good ones too. Some of them we give herewith; the rest will have to wait over till next time, for want of space.

BEES; FOOT-POWER BUZZ-SAWS.

Pa has bees, and I help take care of them. In the spring of 1887 we started in with 33, and increased to 48, eight of which we sold at \$6.00 each. Forty are now on their summer stands. We use the American hive, and like it the best. We use foundation for starters in the sections. We live by a big cranberry patch, and it is a good place for bees. We have a foot-power saw, so we can supply our customers as they come in.

CLAUD M. BURNETT, age 11.

New Vernon, Pa., Dec. 24, 1888.

UNCLE JOSEPH'S BEES.

My uncle has taken a good many pounds of honey. He winters his bees in chaff hives packed with autumn leaves, outdoors. I got a large story-book, and lots of candy and nuts, for Christmas. I have but one brother, named Bertie. He is 12 years old. I am 10. My aunt Mary does not like the bees, because they get in her hair and sting her, and they get after Uncle Joseph too. My grand-

father sits on the stoop and kills all that come near him. They all like honey, but I don't.

Cornwall-on-Hudson, N. Y. MABEL BRIGGS.

PAPA'S PACKING-BOX FOR WINTERING COLONIES.

My papa has nine colonies of bees. He packed them November 5th. He made a rough box of lumber, the front of which looked like this:

It was notched out at the lower board, opposite each colony, the full width of entrance of the Jones hive, which he uses. He puts a little board over the entrance so as to keep the packing from falling down so as not to interfere with the bees coming out. He weighed each hive, and put the weight on a little board inside on each colony. He says it is to know how much honey they eat during the winter. He put a super box on each, filled it full of chaff, and then he filled up the rest with sawdust.

Papa likes GLEANINGS very much. He may omit reading other things, but he never misses GLEANINGS. He lends it all around to every one, I think. I am just 11 years old, and this is my first attempt to write for the public to see. MINNIE COULTER.

Oil City, Ont., Dec. 24.

PAPA'S HIVE-CART, AND FOR WHAT IT IS USED.

My papa has a device for hiving swarms, and for other work about the apiary. It is shown in the photograph which I send you. You see that it is a table upon a wheel, with legs like a wheelbarrow. The wheel is large and strong. When he wishes to have a swarm of bees, or do any other work about the

A HIVE-CART.

apiary he puts his hive or other fixtures upon it, and wheels it wherever he wishes to work. There is a drawer beneath the table, where he keeps his necessary tools. In the photograph you can see a hive on the table. Papa has 200 colonies in that kind of hive. You can also see my father and my younger brother. I was at my uncle's helping him with his bees when the photograph, was taken.

JESSE A. ALDRICH, age 12.

Morristown, Minn., Dec. 6, 1888.

Your papa's hive-cart, we are sure, will work real nicely. The large wheel will cause the cart itself to run very smoothly. You know a large wheel will "walk" right over uneven places on the ground, just like a man, while a small wheel will go "bumpity-bump." But is not the platform of the cart pretty high up from the ground to be handy?

A COLONY WHICH HAS FOR 20 YEARS MADE ITS ABODE BETWEEN THE CLAPBOARDS AND PLASTERING OF A HOUSE.

I will tell you of a swarm of bees that went into a house near here 20 years ago, and is there still. It is a large farmhouse, old-fashioned. The posts, or studding, are 10 inches wide and 4 feet apart. The plastering and clapboards are 10 inches apart. There is a knot-hole on the south side of the house, as large as a silver dollar. Twenty years ago a strong swarm of bees came and took possession of

the space between the clapboards and plastering. They did not swarm for four years, and at the end of that time they cast a large swarm very early; and ever since then, every spring, they swarm from three to four times. In the summer they cover nearly 10 feet square, and in winter they huddle together opposite the parlor stove; and by striking on the wall they answer every time. This year they cast four swarms. The man lost all his bees every year but this one. Two years ago they saw honey dripping out of the lower row of clapboards, and fixed a trough and caught over 100 lbs. It was so hot it broke loose, the man says. Father has offered to take them out for him, but he says he would not disturb them for any thing, as he has prospered in the last 20 years.

FRANK W. REED, age 8.

Milford, Wis., Dec. 10, 1888.

Why, friend Frank, you have told us a very interesting fact indeed. Usually such large swarms in a dwelling will not swarm—at least, not very often. Ten feet square and ten inches thick is a large colony indeed. No wonder they would respond in winter, even though they were less than half this size.

A PIG STORY, AND A GOOD ONE TOO.

Mr. Root:—I saw your notice in GLEANINGS, Dec. 15, and thought, as there was little or nothing to be said about bees, as they are all in the cellar, I would write a letter about something else. Last July, father and Edgar, my big brother, gave us a little pig to raise. He was the runt (you know there is always a runt), and he could not get enough to eat with the others. We started to feed him milk with a spoon, five times a day. He soon learned to come when we went to the barnyard and called, "Come, Johnny, Johnny." We weighed him every week for a while on the honey-scales, afterward whenever we had time. He learned to drink without the spoon in a few weeks, and then we began to give him ground rye, wet with warm milk; and as he grew bigger, we wet it with water. After a while he was able to fight his way among the rest, without any help, and get his share. Then when the rest got big enough to eat from the trough he could not reach, so we had him stand on a stool and then eat. He is now able to eat with the others, and can reach into the trough as well as the next one. When we first took him to raise he weighed 4 pounds. Now he weighs over 80.

We have a thoroughbred Durham calf, about two or three weeks old, and father agreed to give us that for the pig. Father is to have the calves and butter and milk, if our calf lives to be a cow. He is not one of those men who would claim the money after the calf is sold. It is our calf, and will be our cow.

ALBERT HALLETT.

Galena, Ill., Dec. 28, 1888.

Yes, Albert, we are glad you told us about the pig. Perhaps it will induce other papas to give their children something which is *all their own*. It is worth something to a boy to learn to take care of property; not only to take care of it, but to increase its value. The early habits thus acquired will be worth something. But it is cruel, after the boy has worked hard, for the father to sell his pig, calf, or whatever it be, and then pocket the proceeds. There are a few papas who do this, but your father evidently is not one.

NOTES AND QUERIES.

We solicit for this department short items and questions of a practical nature; but all QUESTIONS, if accompanied by other matter, must be put upon a SEPARATE slip of paper with name and address.

MILD WEATHER, AND BROOD-REARING.

OWING to the very mild weather for the past four weeks, queens have begun laying. The mild weather has caused a hundred per cent more stores to be consumed the past month than usual, and I therefore predict loss of bees from starvation this winter to be far in excess of the average.

S. W. MORRISON, M. D.

Oxford, Pa., Jan. 8, 1889.

40 QUARTS OF JAPANESE BUCKWHEAT, FROM 10 OUNCES.

On the 21st day of July I sowed 10 oz. of Japanese buckwheat on a piece of ground one rod wide and six rods long. I harvested forty quarts of fine well-filled wheat. How is that for a yield?

LaGrange, O., Dec. 27, 1888. V. E. FREEMAN.

25 BUSHEL OF JAPANESE BUCKWHEAT FROM 22 POUNDS.

The 22 pounds of Japanese buckwheat I bought of you last spring, yielded me 25 bushels of nice clean wheat, after losing some on the ground. Bees did well on it. They are now in good condition for winter.

G. A. WILLIS.

Enfield, Ill., Dec. 23, 1888.

500 COLONIES IN WINTER.

I only wish you could have been at Syracuse at the convention, or that I could have been in California with you. I go into winter with over 500 colonies. We are having a severe winter.

W. L. COGGSHALL.

West Groton, N. Y., Dec. 24, 1888.

[Friend C., I should have been glad to be with you; but I should have been still gladder to have you and all the other friends of the East with me during my visit in California. As the latter could not be, I am doing the best I can to tell you what I saw there.]

COMBS OF POLLEN; ARE THEY GOOD FOR ANY THING?

My neighbor's bees robbed one of my hives; and when I found it out, the honey was all gone, and the bees also. The frames seem to be nearly full of the pollen. Are they good for anything to use next season, or had I better melt them up?

Westboro, Mass., Dec. 20, 1888. FRANK SIBLEY.

[They will be good to give to another colony in the spring during brood-rearing.]

THE WOOD AND ZINC COMBINED QUEEN-EXCLUDING HONEY-BOARDS.

1. In using the above, is it necessary that the wood strip be just over the top-bar of the brood-frames?

2. Should there be a bee-space between the top-bars and the queen-excluding honey-board?

3. Should there be a bee-space between the queen-excluder and the super, or should the super sit right on the excluder, without any bee-space?

TO MAKE DUMMIES.

Will it do to make a frame, wide enough to fill the space of two brood-frames, out of some light timber, and fill the inside of the dummy or frame with fine chaff, or would thinner ones be better?

Muncie, Ind.

ELIAS W. HITCHINS.

[1. The slats should cover the spaces *between* the frames. 2. There should be a bee-space between the frames and honey-board, and there should also be a bee-space between the super and the honey-board. You can make a dummy in the manner you describe. A less thickness will not be desirable.]

REPORTS ENCOURAGING.

STARTING IN BEE CULTURE.

ABOUT one year ago I accidentally got one of your journals, and became somewhat interested. I bought a colony in March, in the American hive. This cast two strong swarms, both of which I still have, though the first swarm absconded after I had it nicely in the hive for three hours. I followed the vagrant for a fourth of a mile, when it again clustered in the very top of a huge white-oak tree, 100 feet from the ground. After several hours of perilous work I again hived it. This was my "first born," and almost "damped" my ardor in bee culture. Later on, however, I purchased one of your A B C books and a smoker, through Mr. P. C. Clinger of this place; and in my own estimation I am improving.

Milton, Pa., Dec. 24.

P. F. RANGLER.

700 LBS. FROM 11 SWARMS.

My bees did very well this year. I took 700 lbs., comb, from 11 swarms, spring count, and increased to 18 swarms.

WM. C. HERR.

Pike's Peak, Mich., Dec. 27, 1888.

A RUNAWAY SWARM, AND 80 LBS. OF HONEY.

I had a swarm of bees come to me on the 10th day of September. I hived them on foundation, and they made 80 pounds of honey. They told me they would do no good.

A. McDOWELL.

Gaynor City, Mo.

FROM 6 TO 22, AND 325 LBS. OF HONEY.

From 6 stands of bees, spring count, we increased to 22 and obtained about 325 pounds of honey in 1-lb. sections, worth 13 cts. per pound.

Enfield, Ill., Dec. 23, 1888.

G. A. WILLIS.

300 LBS. OF HONEY FROM 5 COLONIES.

I had six colonies but no swarms, and secured about 300 lbs. of honey from five colonies, the sixth making no surplus. All are in good condition for winter.

E. F. BAKER.

Swanton, Neb.

PROSPECTS GOOD.

Spring count was 20 stands, all in good trim except 4. Pounds of extracted honey, 150; sold at 12½ cts. Pounds of comb honey, 450; sold at 20 cts. Total 600 lbs. I had no increase, and united to 18 in the fall, all in good condition for winter, on summer stands. We had a very poor season, as the white clover secreted no honey. Prospects are good for another year.

WM. O. HEIVLY.

Raymore, Mo., Dec. 31, 1888.

FROM 3 TO 20, AND 50 LBS. OF HONEY.

I commenced the season with 3 strong swarms, 2 of which were Italians, and the rest hybrids. I had 13 natural swarms, and took up 4 swarms from the woods, and transferred them to hives, with good success. I now have 20 swarms in prime condition. I did not expect to get much honey, for I worked for increase; however, I got about 50 lbs., and am satisfied with results thus far.

Brimfield, Mass., Dec. 25, 1888.

F. E. BROWN.

MYSELF AND MY NEIGHBORS.

NOTES OF TRAVEL.

He becometh poor that dealeth with a slack hand; but the hand of the diligent maketh rich.—PR. 10: 4.

BEFORE going further I want to digress a little to tell you a short story. Twenty-five or thirty years ago a young man started in Chicago, selling illustrated cards with texts, and, if I am correctly informed, a few other notions and novelties. I am told that he first started out with a half-bushel market-basket. The basket was his own property, and paid for; but the things it contained were mostly sold on commission. This boy was David C. Cook. Printed matter for Sunday-school work seems to have been his hobby. I believe he was also quite an enthusiastic worker in the Sunday-schools. In a little time he had amassed capital enough not only to buy his stock outright, but he got a little printing press, which he used in a room of his own. Before anybody knew it, almost, he was printing his own cards, and some little Sunday-school papers besides. If any of our readers can furnish me a copy of some of those earlier publications, I should consider it a favor. By and by he began to furnish lesson-helps for the Sunday-schools all over the land; and then came out the five-cent edition of books that had previously been sold for \$1.25 or more. GLEANINGS has always been instrumental in pushing the sale of these books. Many thousands of T. S. Arthur's Ten Nights in a Bar-room have been sold at only *three cents* each. David C. Cook published them so we bought them for about 2½ cents each. When his business became so large that he employed half a dozen great printing-presses, the whole business world began to pick and find fault with his cheap editions. Stories were started that he was financially embarrassed, and that he was about to make a failure. The first I knew of it was in seeing friend Cook's vigorous clips at his persecutors, through the Sunday-school helps. It seemed as though he had forgotten the little text that had appeared so prominently on the Sunday-school cards he used to peddle—"Blessed are ye when men shall persecute you and revile you for my sake." I wrote him a kindly letter in regard to the matter, and remonstrated against placing before the children of our Sunday-schools the statement of how he had been wronged. He wrote me a very kind letter by way of reply, thanking me, and he gave me his promise that nothing of the kind should again get into his publications. I had forgotten all about the matter until the day I was riding with my friend "Tommy Irondale" up the Piru Valley, on the way to friend Reasoner's. My companion, however, had so much to say in regard to a certain Mr. Cook, who owned the valley for ten miles or more, that I asked him what Cook he meant.

"Why, Mr. Root, you have certainly heard of David C. Cook, who published the Sunday-school literature?"

"Why, to be sure I know David C. Cook, the Sunday-school man. But he lives in

Chicago, and has a tremendous big business. Is this Cook any relation of his?"

"Why, bless your heart, this is David C. Cook himself, who owns this ranch. He paid \$60,000 for 12,000 acres of land, and this is his town and store and meeting-house, and there is where he lives. He has been here all summer. If you would like to see him, we will stop long enough to have a little chat with him, if he is not too busy."

We found on inquiry that Mr. Cook had gone back to Chicago to see to business, but that he was expected on the evening train. But the foreman at the office kindly gave us all the information he could. Forty-three teams were plowing, harrowing, and cultivating, the day we were there, in his different fruit-orchards. Four hundred acres were being planted to oranges; six hundred more to figs, olives, raisin-grapes, guavas, lemons, peaches, pears, apples, etc. Roads were being made, flumes and aqueducts and irrigating canals were being constructed along the mountain-sides and through the valleys, and a great enterprise was under way. Mrs. Reasoner, where we stopped for dinner, informed us that Mr. Cook himself personally superintended their Sunday-school every Sabbath, at the pretty little church, when he was on the ranch. She said she had been told he now pays taxes on *six millions of dollars*. When I suggested that the Piru ranch would be entirely temperance, the foreman smiled as he told me that no inducement could persuade Mr. Cook to even *plant* such grapes as are used for making wine. When he sells lots to his people, as of course he intended to do, a deed is made out like the following, which was, in fact, taken from a blank deed furnished me by the foreman:

It is provided and covenanted, as a covenant running with the land, that if at any time said second party, his heirs, assigns, or successor in interest, shall, with the knowledge and consent of the owner of said premises, use, or cause to be used, or shall allow or authorize in any manner, directly or indirectly, said premises, or any part thereof, to be used for the purpose of vending intoxicating liquors for drinking purposes, whether said vending shall be directly or under some evasive guise, thereupon the title hereby granted shall revert to and be vested in

The best legal talent has decided that the provision in the deed is valid; and that, upon its violation, the land reverts to the original owner.

I picked up one of his letter-heads from the desk. On it was a map of the ranch, and the following:

THE PIRU RANCHO.—The "Piru" Rancho, or Rancho "Temescal," with adjacent purchases, embraces 13,743 acres of land in a body, situated partly in Ventura and partly in Los Angeles counties, California. The lower end of the ranch is crossed by the Southern Pacific R. R. being two and one-half miles from Camulos station and postoffice, and midway between Los Angeles and Santa Barbara. It is a mountain-valley ranch, containing about 1800 acres of valley land, the rest plowable hill land, with a rich soil one hundred to one thousand feet deep, and steep grazing mountain land. The Piru River runs through four and one-half miles of the ranch, furnishing ample water for irrigating valley lands. It was formerly a part of the "Camulos Mission" Rancho, the home of "Ramona," celebrated for its fine olives and oranges, and has, owing to location, a climate suited to the most delicate trees and plants, making it especially adapted for fine fruit-growing, to which the present owner in-

tends to devote it. The air is extremely dry, clear, and free from fog, frosts, or extremes of heat and cold. Its medicinal springs, similar to those of Newgate, England, are already attracting some attention. The ranch is situated in the oil-belt, seven miles from the largest oil-well in the State, and one-half mile from where wells are now being sunk, and has oil and "brear" on the surface in various places. Owing to mountain ranges, all travel from the north for a large section passes through the ranch, and the town site of Piru City is located on a pretty piece of ground at the railroad crossing.

I inquired of Mrs. Reasoner about his looks and actions. She says he is never happy unless he is directing some new enterprise; that it seems impossible for him to sit still a minute. In the Sunday-school he is a most vehement and energetic worker, although she said that some Sundays he looked as if he were ready to drop, evidently from overwork. If these words should ever meet the eye of friend Cook I would remind him that even the most enduring frame may be taxed beyond its limit. While he may thank God for the wonderful endurance and business energy and capacity with which he has been endowed, he should remember, "What shall it profit a man if he shall gain the whole world and lose his own soul?" It rejoiced my heart to see how the promise has been verified in his case:

Godliness is profitable for all things; having the promise of the life that now is, and of that which is to come.—I. TIM. 4:8.

SKUNKS AND BEES.

There is quite a little difficulty here from these pests. At Mr. Marple's apiary we happened to pass a hive where the bees came out so furiously it attracted attention, when Mr. Reasoner examined the entrance, and at once declared skunks had been troubling them. The ground was dug up around the entrance, and marks of their claws were plainly visible. Friend R. directed the owner to put some strychnine in some comb honey and place it at night near the entrance, to be removed next morning if not taken. He said he had in this way killed more than a dozen. Friend J. J. Cole, at Tropico, where I am at present, says he has been also annoyed, and he poisons them in much the same way. At friend Marple's apiary we found perhaps a dozen hives where skunks had dug around the entrance. Friend Cole thinks they scratch the hive so as to cause the bees to come out, and then kill them by mashing them in the dirt before they eat them.

On account of the late poor seasons, bees are offered at comparatively low prices. An apiary near San Diego was offered us at \$1.25 per colony. There were something over 100 colonies, but they were in a poor sort of hive. Here at Tropico over 100 colonies, in very good two-story hives, are offered at \$2.00 per colony. In both cases the owner wanted to give up the business.

Dec. 6.—The sun rises upon me this morning at the home of W. W. Bliss, Duarte. Friend Bliss is not at home, but I found that his mother knows me well through GLEANINGS; and as she is deeply interested in poultry, incubators, etc., we passed a very agreeable evening. I am glad I love all rural industries and interests that take the

attention of the inmates of Our Homes, and Our Neighbors. All about me here are extensive orange-groves. Right near where I sit writing is a great wagon full of crocheted poles, long and short, to prop the limbs of the orange-trees, to keep them from breaking off. The soil here is almost clear pulverized granite, washed down from the mountains. It is so soft, even before plowing, that the foot sinks into it when you walk. It cultivates most beautifully, and, when worked and watered several years, it seems like soft sand. Every thing grows in it most wonderfully. Corn that has been dropped grows right up, even in December; but I am told the nights are too cold for corn to do *well* now; but many plant it for fodder, even in winter. Squashes, or California pumpkins, grow all over the country, in the greatest abundance, without any irrigation at all, and often without any cultivation. Day before yesterday I saw, on a protected southern slope, great strong plants just out of the ground. They are always seen in waste places the year round, for the very best place to keep them is right where they grow, so that the new crop and those a year old are often found in the same field. I am now right in the narrow fruit-belt I have before spoken of, that runs along at the foot of the mountain. An orange-orchard, with the trees loaded so the limbs are touching the ground, is one of the most beautiful sights, and right here there are miles of such. An irrigating stream, with its pure clear mountain water, running over a bed of gravel, composed of fragments of gray granite, is also to me a most exhilarating sight. The roads here at Duarte are broad, well traveled, and made beautifully smooth with these same granite pebbles.

2 o'clock.—To Huber.—Papa has just visited what is called in California a "chicken ranch." Two young men have got some land and put up little coops, or chicken-houses, all over it. They have three incubators, or machines to hatch chickens, at work; and day before yesterday one of the machines hatched out 200. When the sun goes behind a cloud they just peep, peep, peep, for they haven't any mamma to keep them warm; but when it comes out again, and shines through the little windows, then the chickens all crowd into the sunshine, and are just as happy as can be. At night they all go into a brooder that is warmed by a big lamp. Just beyond these very small ones are some chicks two weeks old; and further on some older still, and so on. The largest ones, that have got their tails grown out, run out in the field where they please. Then they have ducks and turkeys too, and the ducks have nice clear ponds to swim in; and a lot of pretty springs in the hillside furnish clear water for the ducks, turkeys, and chickens. The real little ones are fed about every hour on bread and milk. At noon the boys had prepared a very nice dinner for us; and just before we sat down to dinner, one of the boys bowed his head and asked a blessing. I tell you, papa felt real glad to see them do that, for he knew then they were Christian boys who loved God and were trying hard to do right. Their

flock of grown-up Pekin ducks, with their yellow bills and snow-white feathers, are, as they swim about in their beautiful pond, about the prettiest I ever saw in my life.

Dec. 7.—Once more I am seated out in the morning sun, writing. I am on the edge of a granite rock, almost on the summit of a great mountain. After I got off the train over a week ago, where the lady asked me if I had visited Riverside, the following letter was handed me:

Mr. Root:—If you can make it convenient to visit Riverside (and you will miss a great deal if you don't—of course you *must* see Riverside), if you will drop me a line I will meet you with a team and show you around. I am not proud of my apiary, but I can show you some things that you will be pleased to see. I can take you up on one of those "real live mountains." As I live nearly on the top of one, you can have a chance to climb to your heart's content, or you can go horseback after we get as far as we can go by wagon. I will esteem it a special favor to have you call upon me, and I think we should both be benefited. I can show you the home of the orange, etc. I can show you bees in hives, in houses, in barns, and in the rocks, where you can go and get out honey, and bees without let or hindrance, and I will go and help you. I can show you orange-orchards that net the owners one thousand dollars a year profit, per acre. I have some land that brought me in at the rate of *ten thousand dollars* a year per acre. It was in orange-plants. Come and see me. J. W. KEENEY.

Riverside, Cal., Nov. 26, 1888.

Well, here I am. Right in plain sight in the valley below are seven different towns, or villages: Riverside, East Riverside, Colton, San Bernardino, Ontario, South Riverside, and Pomona. We have been out having a ramble over the mountains. Friend Keeney's hobby is finding springs of water among the mountains. He always thanks God for *whatever* he finds, and of course he finds a *great many* of "God's gifts." He has found nearly a dozen different springs already, and therefore pure spring water flows in pipes almost all over the 160 acres of mountain-top he has taken up. It is up in the mountain-top where nobody else would go, that he made \$1000 raising orange-trees on one-tenth of an acre. His six-year-old prattler, Vernon, when asked if he liked to live up on the mountain, replied, "Yes, I like to live *anywhere*." Dear friend, can you say as much as this little child of the mountains? The other little prattler, that is watching me while I write, is named Mignon, and she is only four years old, and these two have a little nursery of orange-trees, *all their own*, to water and care for.

I not only climbed the mountain, but I sat on the peak, even though said peak was granite, and so sharp I feared it would punch a hole in my trousers. If it did, I proposed to present the rent to my wife as a souvenir of the occasion. Two things contributed to make my seat comfortable in spite of its angular point. First, I was very tired, and panting for breath; second, the view was wonderful. Friend Keeney's house, where I am now writing, seemed but very little higher than the valley; but as I now turn and look back at the peak where I

sat, it seems only a very little higher, as the height of mountains is so deceptive to the eye. The buggy is now waiting for me, and we must go. By the way, perhaps you think it funny the good people out here have nothing to do but to hitch up and drive *me* around, and wait on me. Well, I have thought so too, a great many times, and I am going to try to pay them back if I can.

A CALIFORNIA BEE-CAVE.

Half way down the mountain, friend K. handed the lines to his wife, hopped out of the buggy, told me to come on, and, oh my! didn't he dodge about among the rocks and bushes, along the mountain-side? If some old bear should take a notion to catch *him*, he would roll over *sure*, for that is what I almost did, several times. Pretty soon he came to a bee-cave in the rocks, and showed me where they had been getting pieces of honey out as they wanted it, for years. Yes, and the neighbors did the same; but the bees always fixed it up very patiently, and put in more. Well, he smoked them a little, and we too took out a great slice to eat with our lunch when dinner time came. A week ago he took 80 lbs. of honey from one of these clefts in the rocks, and he is going to save the bees besides. There are great quantities of bees and honey in the rocks, much of it inaccessible without expensive blasting. One man, near Los Angeles, lost his life by falling while trying to get the honey from a bee-cave. It was in a bad place to get at, and the bees stung him so badly that he lost his footing.

C. O. PERRINE.

Dec. 7, evening.—Friend Keeney was right about Riverside, and I am very glad he invited me here. It is a town of about 5000 inhabitants, three weekly papers, two dailies, and no saloons. They first raised the tax to \$500 for *three months*, and for a while no saloon-keeper dared undertake it with such odds against him. Finally one opened, and charged 15 cts. a drink. At the end of the quarter he announced his determination of trying it another three months. At this crisis the Riverside people arose in their might and decided no saloon should ever more disgrace their beautiful corporation limits at *any price*; and to show that they were in earnest they enlarged their limits, in one direction at least, as far as *ten miles*. We drove out this ten miles on what is called Magnolia Avenue. There are miles and miles of beautifully laden orange-trees, with the limbs propped to keep them from breaking; along the roadsides are the most beautiful palm-trees, and almost every other kind of ornamental shade-tree that this world produces. I doubt if there are on the whole face of the earth any more beautiful residences than these. We drove into one of the prettiest orange-groves to eat our lunch; and when friend Keeney introduced the proprietor, he too "knew A. I. Root." Dear reader, who do you suppose it was? Why, Mr. C. O. Perrine, the man who wasted his money on the steamboat apiary, as mentioned in the A B C book. Friend P. bought land here about six years ago, and has, as he says, taken advantage of the boom, and got back the money that went

away when that steamboat proved a failure. As we returned we passed the oldest orange-orchard in Riverside. The owners hauled water in barrels from the river to irrigate them, before the canals were constructed. Some of the trees have borne 20 boxes of oranges in one season; and at \$2.00 per box it is not strange that, with 75 trees to the acre, he should make them average \$1000. Now, dear reader, don't get excited. Riverside is perhaps the best orange district in the world, and this man is an expert. I have passed thousands of acres of oranges that are not paying the interest on the money, and many are abandoned in disgust by their discouraged owners. One of the most beautiful features of Riverside is the bright sparkling water, as it hurries over its gravely bed through the immense irrigating ditches that traverse the land. Some of them are big enough to take quite a pleasure-boat. At one point, where there is a fall of about 30 feet, they are talking of a water-motor to run an electric motor, to carry a train of motor cars through their beautiful valley. What do you think of such an industry as that, ye scientific mechanical geniuses who read GLEANINGS? I tell you, friends, no one knows what a people may do who can say to the saloon-keepers, "Get thee behind me, Satan." "No good thing will he withhold from them who walk uprightly."

Mrs. Keeney informs me that the temperature is about 10 degrees cooler in summer on their mountain, and nearly 10 degrees warmer in winter. This specially fits it for friend K.'s business of raising orange-trees. He uses cheap cotton cloth to protect them from the sun or from the frost, as the case may be. Frames made of lath are also used, and these answer perhaps better than the cloth, for they give the plants sun half the time. In California, all the greenhouses are made with spaced lath instead of glass. Our friend C. O. Perrine made the only greenhouse, covered with glass, I have seen; and he says it was money thrown away, for they make no use of it.

Now a word about being out of work. My two friends Keeney and Woodberry are both carpenters, and both get \$3.50 per day, and I believe both now have more work than they can do; but when they were out of work they were never idle. Each one looked sharp for the chances. One took hold of strawberries and the other seedling oranges. Before leaving Riverside I went into the fruit-packing establishment. After the raisins are dried in the sun, as I have explained, on wooden trays, they are sorted, and the poor ones are put through a machine that breaks them from the stems. Then an ordinary fanning-mill is used to clean the fruit from the stems, when it is ready to be pressed into boxes. Before putting on the cover, however, a lot of the very largest are used to cover the top. I didn't like this; but when I saw every one of the thousands of boxes marked, in large plain letters, "London," I felt like saying, "O Riverside, Riverside! ye who have banished the saloons, have you yet to learn that truth is always better than untruth?"

Friend Keeney has invented, and got into practical use, a machine that sorts the oranges into 8 different sizes, putting each size into a box by itself. I saw the machine at work, and it does it rapidly and surely. A stencil on the outside of the box then tells how many and what size each box contains.

I can not drop Riverside without a word more in regard to her wonderful irrigating canals. One of them is right beside the railroad track, just in front of the depot. The water moves so fast one can hardly run as fast as the bubbles on the surface. One evening I walked out to find the rooms of the Y. M. C. A. Along every street, even in the darkness, I heard the ripples of the happy brooks as they hustled by on their happy errand.

Continued Jan. 15.

JAPANESE BUCKWHEAT.

THE PROFIT MADE IN RAISING IT, ON PAPER.

I BOUGHT one bushel of Japanese buckwheat of you last spring, and I was in hopes of sending a good report; but the frost came too soon. I sold half a bushel to my neighbor, who sowed it about the first of July. The frost came and killed it before one-fourth of it (so my neighbor thought) was ripe; but he secured 25 bushels. My own was sown about one week later, and the frost spoiled it. The bees worked on the Japanese about the same as on the common that was planted beside it, so far as I could ascertain. My neighbor had both kinds in one field, and the common was not worth harvesting, while the yield of the Japanese would have been, but for the frost, 40 bushels at least. I have been thinking of renting land within a mile or two of my place, and sowing it with buckwheat, for the profit I should derive out of it from the grain alone; then the honey I would get from it would be clear gain. I could get the land to plant on shares, or hire it cheap (waste land for \$2.00 per acre). I would figure it in some such way as this:

	Dr.
10 acres of land at \$2.00 per acre.....	\$20
For plowing, at \$1.50 per acre.....	15
Getting in the seed, at \$1.00 per acre.....	10
Seed (I think I can get Japanese seed at \$1.50 or \$1.60, with freight) 7½ bushels.....	12
Cutting grain and setting up, at \$1.00 per acre	10
Thrashing, 4 cts. per bushel, 25 bushels at \$1.00.....	10
	\$77
	Cr.
250 bushels of buckwheat at 60.....	\$150
	77
	\$73

That makes 73 dollars out of the operation. I figured buckwheat at 60 cts. per bushel. It sells here at the mill in Danielsonville, 5 miles from my place, at 65 cts., but it would cost about 5 cts. to market it. I think I could raise 25 bushels per acre without any fertilizer; but if I should put \$50.00 worth of fertilizers on the 10 acres, I should get enough extra buckwheat to more than get my money back; but even if I get but 25 bushels per acre, then it would more than pay me. I know I might fail, and not get one-half the above amount, or perhaps not even 5 bushels; but there is risk in all business.

MEDINA, JAN. 15, 1889.

And he healed many that were sick of divers diseases, and cast out many devils, and suffered not the devils to speak, because they knew him. — MARK 1:34

EARLY QUEENS FROM THE SOUTH.

ALREADY inquiries are coming in. "To whom can I send and get a queen now?" Our friend Nellie Adams, of Florida, comes forward with an advertisement in this issue, but I believe she is the only one. I talked with the folks about it in California, but they are all too well off, or too lazy, or too busy with something else. Now, if there is anybody else in Florida or Texas or California who has young queens on hand ready to mail right off now, let us know, and we will give you an advertisement free of charge.

PRICE LISTS AND CIRCULARS OF APIARIAN SUPPLIES AND PRODUCTS FOR 1889.

We are now ready to make mention of all such circulars and price lists, but we must insist that they have a printed date on them. How else are we to tell whether it is something we noticed last year, or a brand-new one? Sometimes, perhaps, the date is left off by omission; but please remember that nowadays every thing that gives prices or information of any kind in regard to merchandise gives a date. We do not want to waste our time in reading over something that is old and out of date.

THE "WHITE PLUME" LETTUCE.

THE most promising head—the head I wrote about Nov. 15th, died on our hands after it had partially sent up a seed-stalk, so we have got to go back to first principles and start a lot more plants with the seed we raised last summer. The plants are up in the greenhouse, and we can, without question, succeed in getting as nice a head as the one we lost. I presume that none of the friends who received seed from us have done more than to get some nice white heads, without securing seed, unless some friend far enough south secured the seed in the winter. If any such there be, we shall be glad to hear from them.

"GROWING JAPANESE BUCKWHEAT, ON PAPER."

I OMITTED to make any comment or reply to the article on page 67, under the above heading, for the simple reason that I do not know how anybody can advise or suggest in such matters. Many people in many localities would do all and perhaps more than is there figured out; but there are others who would make a failure of the crop, even in the best locality. Then, again, there are experts in farming who would make as good a crop as our friend has figured, on almost any soil, and during almost any season, no matter how unfavorable. The most we can do is to print reports of what others have done;

but it should be borne in mind, when reading these reports, that those who report at all are, for the most part, the ones who have achieved at least a moderate success.

A HINT IN FAVOR OF HOUSE-APIARIES.

ON page 62 Frank W. Reed tells us of a colony of bees under the clapboards of a house, that had wintered safely for twenty years; and the record shows a better condition than we usually get where hives have good care. This colony has had no care whatever, for the very good reason that it was impossible to give them any. Now, why can't our friend, or anybody else, in fact, locate bees under the siding, all over the house? The swarms that come out every year will be so much clear gain, even if you sold them for a dollar apiece to whoever would take them; and it certainly would not be a very difficult matter to give each colony a crate of sections. Does some one urge that the bees would annoy the inmates? Well, then, let some stubborn brother, who loves bees and never expects to get married, conduct the enterprise.

D. A. JONES'S PRACTICAL BEE-KEEPING—A CORRECTION.

OUR friend D. A. Jones is now writing a series of papers on "Practical Bee-keeping," in the *Canadian Bee Journal*. The author is full of bee-lore, and that of a practical kind. These papers will be read with interest, because the matter bespeaks experience. But somehow or another, in speaking of the Parker machines he has got us quoted wrong. He says, "Ernest Root tells of a girl in their employ who can average 3000 (putting in foundation sections) a day with the Parker, and on occasion can put foundation in 1200 sections in an hour." We have not used the Parker machine in our establishment for several years—at least not to any great extent—our girls preferring the foot-power instead. Besides, if we could on occasion put foundation in 1200 sections in an hour, we ought certainly to average more than 3000 per day. The average would be nearer 10,000, would it not? Aren't you thinking of what he said on page 795, of the Oct. 15th issue, friend Jones? We there said that our girls could *fold* (not put foundation in) sections at the rate of 1000 per hour, and could, on occasions, *fold* at the rate of 1200 per hour. With regard to the relative merit of the Parker and the foot-power machines, our experience says that the latter work more rapidly and easily, but the Parker does rather *better* work; that is, the foundation is made to hang straighter after it leaves the machine.

NEST-EGGS FOR COLD WEATHER.

I NOTICE that one of the poultry-journals makes objections to glass and porcelain, that they are too cold for winter use. They give the poor biddies the toothache, probably, when they are obliged to sit on them at a zero temperature. They also object to the heavy porcelain, or china eggs, that, because of their weight, they knock against the good eggs and break them. Both objections, however, I think will not hold good to the eggs we have been selling, made of white glass. These are no heavier than ordinary eggs—perhaps not so heavy; and the material of which they are made is so thin they would not be likely to chill the poor biddy. The basswood nest-eggs are free from both the above objections—they can not be broken, and are less expensive. Ernest says, however, their extreme lightness

causes them to be pushed out of the nest; and my objection to them is, that when they get soiled you can not wash them up as you can the glass ones.

BAROMETERS, AND WHAT THEY ARE GOOD FOR.

WHEN I first got up, on the morning of January 9th, I happened to pass the aneroid barometer hanging in the greenhouse. As the indicator was clear down below the markings of the scale, I concluded the machine had broken; but to be sure, I ran at once over to the house, where hangs a mercurial barometer, only to discover that the column of mercury was also clear below the marks on the scale, and below any thing that I had ever known in perhaps twenty years of observation. I at once announced to the family and neighbors that we were going to have a fearful flood, hurricane, cyclone, or something of the sort. As the morning was perfectly still and warm, nobody paid much attention to my warnings, unless it was Huber. He was greatly exercised for fear the house would sail off into the flood which papa was talking about; but when mamma informed him that brick houses never float away, he admitted the correctness of her reasoning, and put away his dismal forebodings. Toward noon, however, it began to rain, and by noon it rained in torrents. Pretty soon, with the rain came one of the most fearful winds ever witnessed in this locality. By night it was blowing so that people had difficulty in keeping on the sidewalks, and still the barometers stuck to their positions. The wind blew and shook the buildings all night; and in many places we read accounts of fearful losses of life as well as destruction of property. Now, I think it pays to have a barometer. At the noon service I cautioned the hands about leaving things about that would be blown down and destroyed by the wind. I told them to look well to the glass doors about the premises. At the close of my remarks I was informed that one glass door had been smashed already. Such a warning may easily save many times the cost of a barometer, to say nothing of loss of property and loss of life.

THE COMING BEE IN SIGHT.

I INCLOSE a note from the *Youth's Companion*, on the coming bee. H. P. LANGDON.
East Constable, N. Y., Jan. 8, 1889.

TRAVELING BEES.

The distances traversed by bees in pursuit of honey are surprising to a person unfamiliar with the habits of these busy workers.

A bee-keeper one morning dredged the backs of his bees with flour, as they were leaving the hives. He did this by a preconcerted arrangement with a friend who had a fine clover-field in bloom forty miles away.

The day following the experiment, he received a letter from this friend, stating, "There are plenty of your white-jacketed bees here in my clover." It was truly a wonderful instinct that sent the bees so far from home in quest of honey.

Well done, friend L. But is not the *Youth's Companion* getting out of its beat just a little? Their item would do nicely for a joke; but the trouble is, the general press will go to work and copy it, and spread it broadcast, taking it for fact. True, it is not so bad as the stories about artificial honey and artificial eggs; but still it should be corrected at once, and we hereby beg the publishers of the *Youth's Companion* to at once inform their readers that their statement is a blunder. It should have been four miles instead of forty. The extreme limit of reports like this—that is, tests made by sprinkling the bees with flour—has shown that they may fly in quest of stores as far as perhaps eight miles. In all of the reports that have come in, not one has ever gone beyond this; and the general testimony

seems to be to the effect that bees seldom go beyond two or three miles. When the Italians were first introduced in Medina County I took pains to go out with the horse and buggy in different directions, and at different seasons of the year, and it was only in extreme cases that I found them as much as three miles away from home. In view of the fearful blunders that journalists have been making in matters out of their beat, would it not be a wise precaution to submit questions pertaining to some particular branch or industry to experts or editors of journals pertaining to that particular industry? It is an easy matter to start a misleading statement; but it is a tremendous task to chase it out and head it off when it once gets into print.

DIMENSIONS OF FRAMES IN COMMON USE, ETC.

THE *Bee-Keeper's Guide* stirs things up lively in its issue for Jan. 1, on the matter of frames. A. I. Root and Prof. Cook are the parties who need correcting. For myself, I can only repeat that, when I commenced making Langstroth hives, I sent to father Langstroth and had him express to me a frame of exactly the dimensions he would have it. He sent me the frame, and I think I have it yet up in the attic. From this frame I took my figures, not noticing that it did not agree exactly with the dimensions given in his book. This frame, as I started it, is also exactly right for eight Simplicity sections, $4\frac{1}{4} \times 4\frac{1}{4}$. Now, if we go back to the old dimensions of the old frame, it will not hold eight sections; and, as a matter of course, we want the wide frames to have exactly the same dimensions as the brood-frames. In regard to the American frame and American hive, which was originated by H. A. King more than thirty years ago, I also got the dimensions of my American frame from friend King himself. This, however, was after he had decided to change the dimensions of his frame from what it had been originally. If I am correct, the first American hives made were changed so many times there was for a time no particular dimensions to either the frames or hives. Perhaps H. A. King or his brother can tell us something about the correct dimensions of the American frame. At the same time, I think we can show that there are more frames of both Langstroth and American, of the dimensions we give, than of all the rest in the world, by a very great odds. This being true, it would be folly to attempt, at this late date, to make any change. It now remains for Prof. Cook to stand up and tell us why he doesn't say whether the dimensions he gives in his Manual are inside or outside dimensions. Inasmuch as the outside dimensions must be exact, while the inside may be just as it happens (according to the thickness of the material), I do not see why anybody should ever think of taking dimensions of frames to refer to the inside. Permit us to thank friend Hill for his very kind mention of our latest edition of the A B C book. He says: "It is the largest and most extravagant publication of the kind, and one must see it to appreciate or comprehend its excellence. It is the accumulation of years." We don't exactly know what he means by the word "extravagant;" but from the general bearing of the notice we feel sure it can not mean any thing bad.

DADANT'S FOUNDATION FACTORY, WHOLE-SALE AND RETAIL. See advertisement in another column. 3btfd

The value of a one-piece section depends on its folding without breaking. Our process of manufacture secures that end. Our catalogue explains how it is done. Our No. 1 sections

are perfect in all respects, and No. 2 are not imperfect enough to impair their utility. We also make the nicest of **WOOD SEPARATORS**—keep **DADANT'S FOUNDATION**, and furnish three kinds of **BERRY PACKAGES**.

Address, as in cut, for catalogue and special prices. *Mention Gleanings.* 1-12db

BEE-HIVES, SECTIONS, ETC.

WE make the best bee-hives, shipping-crates, sections, etc., in the world, and sell them cheap. We are offering our choicest white one-piece $4\frac{1}{4} \times 4\frac{1}{4}$ sections, in lots of 500, at \$3.50 per 1000.

Parties wanting 3000 or more, write for special prices. No. 2 sections, \$2.00 per 1000. Catalogues free, but sent only when ordered. 1tfdb

GREGORY'S SEED CATALOGUE.

1889.

Come, Fellow Farmers!

It is the good things and the new things you want. Here is a Catalogue full of them! Do you want tested seed, raised from stock selected with extra care, grown from the best strains, got from the originators? I aim to have mine just such. Do you want new varieties that are really good, and not merely novelties? I aim to have mine such. Do you want seed that the dealer himself has faith enough in to warrant? I warrant mine, as see Catalogue. Do you want an exceptionally large collection to select from? Mine is such. Do you want them directly from the grower? I grow a large portion of mine—few seed-men grow any! My Vegetable and Flower seed Catalogue for 1889 FREE to everybody. JAMES J. H. GREGORY, Marblehead, Mass.

HONEY COLUMN.

CITY MARKETS.

MILWAUKEE.—*Honey.*—This market for honey is dull; very best sells slowly. Inferior qualities neglected. Choice white 1-lb. sections, 17@18; same, 2-lbs., 15@16; good dark, 1-lbs., 15@16; same 2-lbs., 14@15; fair, 1-lbs., 12@14. Damaged and broken, not wanted. Extracted, white, kegs and ½-bbls., 8½@9; ditto, amber, 7½@8; white, in pails and tins, 9½@10; dark, bbls. and half-bbls., 5½@6½.
Beeswax, 22@23. A. V. BISHOP.
Jan. 10. Milwaukee, Wis.

ST. LOUIS.—*Honey.*—The movement in honey is very slow. Hard to realize satisfactory prices for the shipper or ourselves. Choice white clover, comb, sells freely at 14@15. But extracted in cans about 7½@8. In bbls., 5@6½ as to quality.
Beeswax, 20. W. B. WESTCOTT & Co.,
Jan. 26. St. Louis, Mo.

CINCINNATI.—*Honey.*—Demand is slow for all kinds of honey, with a comparatively small supply on the market. Extracted honey brings 5@8 on arrival; comb honey, 12@16, in the jobbing way.
Beeswax.—There is a good demand, which brings 20@22 on arrival for choice yellow.
Jan. 21. CHAS. F. MUTH & SON,
Cincinnati, Ohio.

NEW YORK.—*Honey.*—The extremely warm weather has brought business in honey to a standstill, and we quote nominally fancy white, 1-lb. comb, 14@15; 2-lbs., 12@12½. Fair white, 1-lb., 12@13; 2-lbs., 10@11. Buckwheat, 1-lb., 10½@11; 2-lbs., 10.
Extracted, basswood and clover, 8@8½. Buckwheat, 6@6½. We expect a good trade in buckwheat extracted, during next month.
Jan. 19. F. G. STROHMEYER & Co.,
New York City.

DETROIT.—*Honey.*—Best white in one-pound sections continues to be quoted at 16@18, with a little less in sight; market will be bare of comb honey before the new crop will find its way in.
Jan. 21. M. H. HUNT,
Bell Branch, Mich.

KANSAS CITY.—*Honey.*—We quote: 1-lb. comb, white, 16; fall, 14; California white, 16; 2-lb. California white, 14; 2-lb. extra Cal'a, 13. Extracted, Cal'a white, 8; Cal'a amber, 7. Beeswax, 20@22.
CLEMONS, CLOON & Co.,
Jan. 22. Kansas City, Mo.

ST. LOUIS.—*Honey.*—Market quiet, but firm. Comb, choice clover, 13@15; dark, 8@10; strained and extracted, in barrels, choice, 6@6½; cans 7@7½; dark, 5@5½. Cans, 6@6½. Beeswax, prime, 20.
Jan. 22. D. G. TUTT GRO. Co.,
St. Louis, Mo.

NEW YORK.—*Honey.*—Market quiet; fine goods very scarce; but as there is no demand for it, there will be no goods left over this year.
Jan. 19. THURBER, WHYLAND & Co.,
New York City.

COLUMBUS.—*Honey.*—Our market remains the same. White comb in 1-lb. sections, 16@18; no demand for larger sections. EARLE CLICKENDER,
Jan. 19. Columbus, Ohio.

ALBANY.—*Honey.*—Market slow and prices weakening some.
H. R. WRIGHT,
Jan. 26. Albany, New York.

BOSTON.—*Honey.*—No change in market prices.
Jan. 21. BLAKE & RIPLEY,
Boston, Mass.

FOR SALE.—One ton of white extracted honey, in kegs and barrels; also amber, or fall honey, of excellent quality, in same packages. Write for prices, stating amount desired. FRANK McNAY,
Mauston, Juneau Co., Wis.

FOR SALE.—First-class extracted honey in 60-lb. tin cans. Having just been liquefied it will pour from cans easily. Will take 9 cts. per pound. Samples sent for 2-ct. stamp. R. I. BARBER,
818 E. Washington St., Bloomington, Ill.

FOR SALE.—I have about 1500 lbs. of nice light honey, fresh from sealed combs, mostly clover and basswood, that I will sell in 175-lb. cans at 8 cts. per lb., or in lots to suit. Sample by mail free.
OLIVER FOSTER, Mt. Vernon, Linn Co., Iowa.

FOR SALE.—I have a quantity of extracted honey in 50-lb. kegs, which I will sell at the following prices: 8c for the white and 7c for the amber, f. o. b. The honey is first class. C. H. STORDOCK,
3 64b Durand, Ill.

Beautiful Laced Wyandottes.

OUT-APIARIES.

SHALL I START ONE?

THIS question is likely to come up in the minds of not a few; and although each one must answer for himself, there are a good many side questions that may present themselves for reply before the main question is reached. On some of these I will try to throw some light, without going through the formality of stating the questions. If you decide that you will keep three or four hundred colonies of bees, it is a pretty clear case that you can not profitably keep them all in the home apiary. Just how many you can profitably keep there, is an exceedingly difficult thing to determine. Supposing that, by a series of careful experiments extending over fifty years, it has been pretty satisfactorily determined that 93 colonies is the largest number that can, on the average, be profitably kept in Mr. Smith's apiary, 20 miles distant, it by no means follows that the same series of experiments would reach the same conclusion on your ground. The same kind of flowers may not be on your ground; the soil may be different, or, if these be alike, the rainfall may differ; and supposing no difference can be detected in any of these, how are you going to measure the number of flowers to be found on the one, two, or three thousand acres that constitute the range of the bees in each apiary? Suppose you have a crop of 6000 lbs. from 80 colonies one year, and the next year from 100 colonies you get 5000 lbs., it does not certainly follow that 100 colonies overstock the ground; for in the last case there may be a bad year, and it is possible that the very next year may

be so much better that 100 colonies shall store 10,000 lbs. surplus. So you see it is a very difficult thing to decide what is the largest number you ought to keep, in order to the greatest profit. I wish I could give you some rule by which you might determine the matter, but I can not; and I am obliged to confess that, after a good many years of experience, all of it on the same ground, I am not able to say with any degree of confidence whether 75, 100, or 125 colonies will bring me the greatest profit. The best I can do is to say that, if your location is an average one, it is not likely you would better keep more than 75 or 100 colonies in one apiary. If any one should accuse me of presumption in attempting to speak so definitely, I am ready to bear the reproof very meekly, and confess that I know little about it. Close observation for a series of years may help you to a more reliable guess as to your own locality.

If you find that 50 or 75 colonies occupy the most of the time that you can spare from other business, it is hardly advisable for you to attempt a second apiary, for you will find that it will make a draft on your time in a different way from the home apiary. Often there is some little thing to be done which needs only a few minutes to do; but if you must go three or four miles to do it the case is quite different.

Suppose you find, or think you have found, that, after you have reached 75 colonies, the next 25 will do a good deal better in an out-apiary, you must still keep in mind that this 25 will entail more expense (I include time and labor, of course, in expense) in proportion than the first 75, and the probability is that you would better keep the 100 at

home if your total crop is greater than from the 75, even if the average yield per colony from the 100 be less than from the 75. In other words, it is well to crowd the bees at home a *little*, rather than to start a second apiary. Whether you need to keep some one watching for swarms, cuts some figure in the account. There may be cases, however, where the extra 25 would turn the balance in favor of an out-apiary. If it is your intention to continue to increase, and you have reached, or nearly reached the limit of the home apiary, and you expect to start an out-apiary next year, it may be better to start it this year. The practice this year on a smaller number will be of advantage to you. In the matter of hauling alone, you need experience—at least I did. Mishaps were quite too common with me at first; and if I had had a large number to haul, the matter might have been serious. Another reason for commencing this year, rather than next, is, that you have no certain tenure of territory; but if you commence an out-apiary this year you may be less likely to see some one else occupy the same ground next year. C. C. MILLER.

Marengo, Ill.

Another thing that you can determine by starting out-apiaries is the value of localities. Some find the out-apiary better than the home apiary, and others not nearly so good; and I remember that, in some cases, there seemed to be a marked difference, without any explanation as to why it was so. This marked difference showed itself year after year. By trying 25 colonies at a time, or even a less number, you can decide what a locality is worth. If it is not as good as your home apiary, you can make a test in another direction. Sometimes an out-apiary will give stores when the bees at home are getting none at all. This is often the case where you can go in the direction of a swamp, river bottom, or something of that sort.

INCREASE, OTHERWISE THAN BY NATURAL SWARMING.

FRIEND DOOLITTLE TELLS US HOW TO MANAGE IT.

A SUBSCRIBER for GLEANINGS says he can not stay at home and care for the swarms which may issue from the 30 colonies of bees which he has, and wishes me to tell him how he can manage next season so as to increase his bees and still have them do good work in making comb honey. After trying nearly every plan of artificial increase which has ever been given, I am satisfied that none of them will give as good results as will natural swarming; but where one is situated as is the writer of the above, of course a substitute for the good old way will have to be resorted to. Knowing that there were times when increase other than natural swarming would be very desirable, I kept a record of all of my experiments while trying the various plans of making swarms, as given at different times to the public, and, according to my views, the two following come the nearest to nature's way of any now before the world. The first is a plan which was adopted by Elisha Gallup, and given to the world some twenty or more years ago, while the latter plan is one I made up out of different hints I picked up here and there. The Gallup plan I have practiced quite ex-

tensively for years, while the other I use almost altogether at the present time. All the particular difference there is in the two plans is that, with the latter, a new queen is given to the swarm, leaving the old one to continue to do duty in the old hive; while with the former the old queen goes with the swarm, the same as she does in natural swarming, thus leaving the bees to rear a queen of their own. By giving each part a laying queen, great gain is made; still the Gallup plan is a good one where one can not rear the queens before he makes the swarms, or feels too poor to buy them. None of the plans of artificial increase should be used till the hive is quite well filled with bees, and the bees themselves are preparing for swarming. When the proper time has arrived, go to any colony from which you wish to take a swarm, and, after having removed the cover and quilt or honey-board, drive the bees out of the way with a little smoke so that you can shave the capping off from some of the sealed honey at the tops of the frames, unless you think they have plenty of unsealed honey in the hive. Just previous to doing this, you should find the queen, and cage her on one of the combs with one of the wire-cloth cages which will push into the comb, as has been so often described. Having both of the above done, close the hive and beat on it with the fist, at the same time blowing smoke in at the entrance, just enough to frighten back the guards as they come out to drive off the intruder. Having the guards all turned back, give the hive several sharp blows, enough to cause the bees to thoroughly fill themselves with honey; and if more than one swarm is to be made, go to the next hive and prepare them in the same way, while the first are filling themselves; otherwise you will have to wait till the bees have their sacs full. When this is accomplished, set the cap of any hive on a wide board a little way off from the old hive (any box will do), and proceed to shake the bees off the frames till you think you have about three-fourths of them, shaking them in front of the cap or box on the wide board, into which they will run as fast as they are shaken off, if the same is raised up a bee-space on the side next where they are shaken. Lastly, take the frame having the queen on it, and, after uncaging her, shake her and the bees off this frame, letting them run in with the others. Now close the hive, when the returning bees from the field and what were left on the combs and about the hive will make the colony in about the same condition it would have been in had it cast a swarm. Next take the cover having the bees in it; carry it to the shade of some tree, and, after setting it down, lean it up against the tree with the open side out, exposed to the light. Leave them thus while you are making other swarms, or for about an hour, when they will conclude they are a separate colony, and will behave just like a natural swarm, having clustered in the box the same as a swarm does on a limb. Now have them as you would a natural swarm, and they will work the same, or as nearly so as is possible to have bees do outside of natural swarming.

The next way, and the one which I prefer when I have laying queens to spare, is to proceed the same as above till you get ready to shake off the bees, when they are to be shaken into a box instead of in front of a cap. This box is to be made of a size to hold about half a bushel, the two sides of which are to be of wire cloth, one permanently

nailed on, and the other is to have the wire cloth nailed to four small strips, so that four small nails, one through the center of each strip, will hold it fast to the box, yet make it readily removable when we wish to get the bees out. In the top of the box is to be bored a hole of the right size to admit the small end of a large funnel, such as is used in putting up bees by the pound, and over this hole is to be fixed a slide so that it can be closed as soon as the bees are in. Having the box and funnel, proceed to shake the same amount of bees down through it into the box as you did in the former case; but instead of putting the queen with the bees in the box, uncage her and set the frame having her on back in the hive. In this case you leave the old colony in the same conditions in which they would have been had they cast a swarm, with the exception that they have the old queen with them, so as to keep up egg-laying all the while. Now carry your box of bees to your bee-cellar, or some other cool dark place, and leave them undisturbed for four hours, when you are to go and get a queen in a round wire-cloth cage, from one of your nuclei, or one which you have bought; and after getting where the box of bees is, jar the bees to the bottom of the box, by setting it on the floor suddenly, so that they will not be running out while you are putting in the queen, and immediately let your queen run through the hole into the box. Now close the hole and leave the bees till sunset or the next morning, when you will find them clustered and ready for hiving, the same as a natural swarm would be, having accepted the queen which you gave them, as their own mother. Hive as before, and the work is done.

In using this latter plan it is best to take the bees between the hours of 10 and 12 A. M. In writing this out it seems like a good deal of work; but where making many swarms, the work goes on rapidly, as the bees are filling themselves while you are working, so that there is no waiting. In this way swarms can be made about as fast as natural swarms could be cared for, while they work nearly as well after they are made.

Borodino, N. Y., Jan. 17, 1889. G. M. DOOLITTLE.

Friend D., if I may be permitted to make a suggestion I would tell a novice not to risk shaking the queen with the bees in front of the hive-cover. I have seen the queen a good many times, instead of dropping down to the bees, take wing; and when they are on the wing they do not always go in with the bees. Several times I have had them go back to the old hive, where I would find them on one of the combs. I would take the queen off and set her down among the moving bees, and be sure she crawled into the box, then there will be no danger of getting two queens together. I have also found bees from some colonies that would, a large part of them, return to the parent hive after they went out for pollen or honey. Your manner of manipulation, however, may prevent this largely; and perhaps if you have three-fourths of the bees *with the old queen also*, the ones that went back would not make any material difference. Lastly, I would by all means put a comb with unsealed brood, with an artificial colony of any sort. I have tried over and over again this comb of brood, and so have our boys, and we are so

fully satisfied that it helps to make the bees stay in a new hive, that I never omit it. Sometimes, where we find the bees have absconded, I ask the question, "Did you give them some unsealed brood?"

Almost invariably the reply is, "Why, I was too busy just then;" or, "I declare, I forgot it," or something of that sort.

JAPANESE BUCKWHEAT.

COMPARATIVE TESTS WITH THE COMMON BUCKWHEAT.

I SEE several reports of the Japanese buckwheat, but you have never yet, I believe, treated the readers of GLEANINGS with cakes made of Japanese buckwheat, so, now, let's have some of them. But before we can have the cakes we must produce the buckwheat, so I will report that first.

Last season I sowed it at three different times, as much for my bees as for the grain. The ground was an old worn-out piece of farm land that had been farmed to corn and wheat for many years, until it would not produce a crop of either, worth the cost of raising. I do not know the amount of land or the amount of seed I used, but probably about two acres of ground. The seed was not good, as some portion of it had been sprouted when harvested, and so did not grow when sown. It stood much too thin. It might easily have been as thick again on the ground. As for bee-pasture, it was a fair success. They worked on it pretty thickly. I did not, however, get any direct surplus honey, yet I could distinctly tell the buckwheat flavor in some of it. Well, I got about 50 bushels of nice grain, which I have refused one dollar per bushel for. I also had a fair chance to test it with the common kind.

A neighbor sowed 3 acres, on about the same grade of land, with the common seed. I wanted him to sow the Japanese but he thought he could not stand the pressure of four dollars a bushel for the seed. He harvested 26 bushels from the 3 acres. He has since said if he had sown my kind he would have got at least 75 bushels.

Now, here come the cakes. I took 3 bushels to the mill, and charged the miller to be particular to have the mill well cleaned, so there should be no mixture of any other flour or corn meal with my flour, that could possibly add to or detract from its bulk or quality, as I wanted to have a fair test of it. His report is, first, that it gave about five pounds more flour to the bushel than any other he had ever ground; and, second, that it made the whitest flour he ever saw, from buckwheat. And now I am having the very best cakes every morning that I ever had in my life. My cook says that I eat from 12 to 16 every morning. Be that as it may, my breakfast is a good one; and by the way, she puts away the Japanese buckwheat cakes, she had better keep still or I shall tell how many she eats.

I had a small plot of ground that I raked over and sowed the Japanese buckwheat on, as late as the 9th of September, thinking it might furnish a few blossoms for the bees; and when the frost killed it it was 18 inches high, and perfectly loaded with set grain, some of which began to ripen. If it could have had two weeks more time it would have given a pretty good crop of grain. A. A. FRADENBURG.

Port Washington, O., Jan. 21, 1889.

37 BUSHELS OF JAPANESE BUCKWHEAT FROM $\frac{1}{2}$ BUSHEL OF SEED.

I got one bushel of Japanese buckwheat of you last summer. I let a neighbor have half of it. I sowed the other half on one acre of land, and harvested 37 bushels of nice buckwheat. I am sure there would have been over 40 bushels if it had been well saved. Other buckwheat didn't yield half as much. I could not tell any difference in bees working on the two kinds. I sowed on the 26th of June.

Jonesboro, Ind.

C. J. EVANS.

43 BUSHELS OF JAPANESE BUCKWHEAT IN TWO YEARS.

I started with $\frac{1}{4}$ lb. of Japanese buckwheat, which I got of you two years ago. From the $\frac{1}{4}$ lb. I harvested 47 lbs. I sowed the 47 lbs. on $\frac{3}{4}$ of an acre, and it yielded 43 bushels, or about 50 bushels per acre.

PERLEY LANGWORTHY.

Riceville, Pa., Jan. 9, 1889.

In addition to the above, and what is said about this buckwheat in the last issue (pp. 58 and 63), we would refer you to pages 95 and 99 of this issue.

BEARS AND HONEY.

SETTING OUT FRUIT-TREES; MOVING BEES SHORT DISTANCES.

I HAVE just been reading with much interest A. I. Root's travels in California, and his visits with the bee-keepers. Oh how I should like just such a trip! But I should have to stay long enough to kill some of those bears and other wild animals. The idea of a man letting a bear come to an apiary of 11 colonies and eat them all up, and then letting the old fellow go away in peace is amusing. If it had been my case, I would have made him pay for the bees, if there was money value enough in his hide and meat and tallow to do it. But if there was no value in the old fellow, why, then I would have killed him to get even with him, and get him out of the way.

HOW TO SET OUT STRAIGHT ROWS.

On page 979, Dec. 15, Mr. Root speaks of seeing orange-trees that were set in such perfectly straight rows, and wants to know if some of the readers of GLEANINGS can tell how to do it. If the ground is not too hilly, or surface too rolling, get out as many small stakes as you propose to set trees. Make the stakes about one inch in size, preferably round, and in length about two feet. The next thing to do is to get those stakes stuck in straight rows. You can accomplish it very nearly by marking off the ground with a corn-marker, marking the ground both ways. Stick the stakes in the crossing at every third or fourth crossing, according to how close you want the trees. With a man to sight through the rows, and another man to move the stakes a trifle one way or the other, if they are not quite right, straighten the rows. It is a great deal easier to move a stake a little than to move a tree a little after it is set. Having straightened the rows, set the trees. First we want a setting-board, which can be made out of a piece of fencing, 6 inches wide and 8 feet long for small trees. Bore a $1\frac{1}{2}$ -inch hole exactly in the center of the board, both endwise and sidewise; then, say 3 inches from each end of the board, bore a $1\frac{1}{2}$ -inch hole. Saw out a strip crosswise, $1\frac{1}{2}$ inches wide, the center of the board, on one side, until it meets the auger-hole. Our board will now have a notch in the center and a hole in each end, like this:

We want two stakes, about a foot long, and small enough to go through the end holes of the board.

Lay the board on the ground and crowd it up till the stake is in the center notch, snug into the notch in the board. Let the stake be in the notch as far as it will go, then stick your two short stakes into the holes in the end of the board, and down into the ground firmly. Pull up the center stake and take away the board. Dig out the place for the tree to stand in, then put the board back again, so that the two small stakes are in the end holes of the boards as before. Place your tree in the center notch of the board, and fill in with dirt. Be sure that the tree stands straight. When the place is about filled up, the board can be taken away so that a nice job can be made. The tree will, of course, stand in exactly the same place that the stake did. We can now pull up our two small stakes, and go to another stake and set another tree in the same way.

MOVING BEES SHORT DISTANCES.

We often read in the bee-papers directions for moving a hive of bees in the apiary, something like this: Move the hive a foot or two a day, until it is in the exact place where it is wanted. Now, friends, I would not do any such thing. Some time when the bees are all in the hive I would just pick it up and put it where I wanted it, and done with it. We move bees more or less every spring, to equalize our yards; in that case we move them four or five miles or so. But last spring we wanted to move about half of one of our out-apiaries, to get them further from the public highway. There were, in quadruple hives, 69 colonies in 4 rows, running east and west. We wanted to move the east

half, and put them *west* of the west half, a distance of eight or ten rods. This apiary was 5 miles from home. To go out there and move those hives a foot or two a day, mixing them up among the other hives as we worked them along, would have made a big job, and no doubt would have resulted in nearly all of the young bees being left behind in the hives that we passed in moving. Well, we made all of the new stands at the west end of the apiary ready to set the hives on, and got every thing ready to move, and then went home. The next morning, May 18, it was very cloudy, and raining a little, and it promised to be a wet day. We put the wheelbarrow into the wagon, and started. As bees were not flying when we got there, we just set one of those big hives on to the wheelbarrow, and wheeled it to the stand where we wanted it, and there located it. We then went back and got another, and kept on until we had moved all we wanted to, about 35 colonies. Shortly after all were moved, the weather cleared up and the bees went to work; and before noon the moved bees were bringing in pollen. There were a few bees flying about the old stands, looking for home, for about two hours; after that, every thing was running as usual. As far as I could see, the moved bees did just as well as those not moved. Then what is the use of all this fussing, hitching along a little to-day and a little to-morrow?

E. FRANCE.

Platteville, Grant Co., Wis.

Friend F., your remarks in regard to setting trees, in connection with what is said on page 87, will doubtless enable any one to work rapidly and accurately. I think I should prefer to stretch a line, however, rather than to have so much sighting.—I am a little surprised at what you say about moving bees short distances. I am very well aware that some colonies stick to their old home, without any trouble; and at other times the loss of bees in spring time will so reduce the colony as to prove fatal to it. At one time I attempted to move a strong colony of Italians during the working season, from one part of our town to the other. Enough bees went back to their old stand to make a small-sized swarm. These were brought home on a comb, placed in a box, and shaken in front of the hive. They ran in like a natural swarm; but the next morning, nearly if not quite all of them returned to their old stand, laden with pollen and honey. This they kept doing until I got tired of carrying them home every night. Now, it is possible, but not very probable, that, had I left no comb or box for them to cluster in, they might have returned to their new location. At another time I purchased a box hive of a neighbor, moving it perhaps an eighth of a mile. This moving was done in the winter time. Within ten days or two weeks, however, we had a very warm day, and the bees flew profusely. Well, so many bees went back to their old stand that the owner told me there was a pretty fair swarm circling around where their hive used to stand. That night they scattered about on the trees and bushes, and were chilled to death. The next day, more of them went back; and the result was, the colony that cost me \$5.00 died for lack of bees to keep the brood warm, I

have seen this same thing happen so often, that I think novices should be very careful indeed about moving bees short distances. When they are moved so far that they do not meet familiar objects on their first flight, of course they will all go back to the hive. An old veteran like yourself, who keeps an eye on the movements of the bees, would probably not lose very many.

FALSE STATEMENTS IN REGARD TO THE HONEY BUSINESS OF OUR COUNTRY.

As a protection to our bee-keeping population, we propose in this department to publish the names of newspapers that persist in publishing false statements in regard to the purity of honey which we as bee-keepers put on the market.

FRIEND ROOT:—The inclosed clipping was taken from the *Lutheran Observer* of a recent date. If you find room in *GLEANINGS*, please insert it and give a reply to such damaging nonsense as that.

H. W. WALKER.

Somerset, Pa., Jan. 15, 1889.

Below is the clipping referred to:

SCIENTIFIC LEGERDEMAIN.

In these days of adulteration,

When all things are not what they seem,
And every thing is something else,

it is no more miraculous that olive oil should be squeezed out of a peanut than that Java coffee should be ground out of the chicory root, or that black pepper be only another name for pulverized cocoanut shells. Science is now making such rapid strides toward helping us in our gastronomic needs, that Nature herself must get out of the way or she will be run over. Even the poor honey-bee was accused, not of laziness, for that would have been too palpable an injustice, but of being too slow, and spending too much time over the clover heads.

"I will remedy that," said Science.

And she did. Shutting up the bees, she knocked the head out of a barrel of glucose and told them to go to work and help themselves, which they did faithfully. Their long journeys to and from the flowering fields being done away with, they had nothing to interfere with their getting down to actual business. The scheme was a success, for the honey was piled into the combs in treble abundance and in one-third the usual time.

And yet Science wasn't satisfied.

Greedily she put her wits to work.

"What's the use of going to the expense of buying bees? I can make the comb quicker and as well as they; and as for the honey—well, glucose is honey!"

And so the occupation of the honey-bee being gone, so far as it has any hand in what is known as the "honey of commerce," it now confines itself in a small way to home manufacture, samples of which, if the reader particularly wants, he must particularly search for.

The above has just commenced going the rounds of the press, and it really seems as if the religious press were worse than any other in taking up and scattering broadcast these false and slanderous statements. Friend W., as you will notice, says he took the clipping from the *Lutheran Observer*, and we notice that they give credit to *Table Talk*. Now, friends of the *Observer* and *Table Talk*, will you not correct the misstatements which I presume you have unwittingly made? For three years past we have been fighting down this falsehood. Many papers have recalled the statement, but it seems to be cropping out again. Surely you would not knowingly injure an honest class of people, if you knew it. More than two years ago I published a standing offer of

one thousand dollars to any one who would tell us where this spurious comb honey was manufactured. Every one has been obliged to give up—there is no such thing, and there never was. Will you not at least briefly correct the wrong you have done? Bee-keepers are as anxious to put down fraud and adulteration as are the cheese and butter makers; but they do not like to have their industry damaged by having the people prejudiced by false statements like the above.

THE GREAT NOVELTY OF 1889.

A LIMA BEAN THAT GROWS ON BUSHES, AND DOES NOT REQUIRE POLES.

ALTHOUGH I have never seen this new lima bean except in a dry state, yet I am so well satisfied of its excellence that I purchased 1000 25-cent packages. In regard to the origin, we extract the following from the February issue of the *American Agriculturist*:

The history of the new bush lima bean is rather interesting. As far as can be traced it originated in the mountains of Bedford County, Va., in a locality known as the "Peaks of Otter," in the garden of a humble colored man, who was bright enough to notice a single plant that formed a bush

delicious lima beans, and is at least two weeks earlier than any of the climbing limas, being fit for market about the middle of July, in York State, and from that on until frost. The only thing against it that I know of is its small size compared with the limas that grow on poles, the dry beans in the packets being about the size of those shown in the cut, *only after being soaked in water over night*. Perhaps, in a green state they are considerably larger. We are not permitted to sell them for less than 25 cents each packet; 5 for \$1.00, or 12 for \$2.00. A packet contains about 25 beans. We are permitted, however, to offer it as a premium as follows: We will send a packet to every present subscriber who will send us \$1.00 and the name of a new subscriber to GLEANINGS. If you are too busy to hunt up a subscriber, send us \$1.00 to extend your subscription for 1890. We append the following testimonials from Henderson's catalogue:

The Dwarf Lima bean was a surprise indeed. Who would ever have thought it possible to transform the climbing, rampant-growing Lima bean into a bush! But here it is before my eyes, a bush Lima, loaded with pods, and that so early in the season as to remove one of the principal objections—their late ripening—to growing Lima beans. This, combined with its independence from the troublesome and unsightly poles, must make this new vegetable wonder a welcome acquisition to every garden.—DR. F. M. HEXAMER, Office *American Agriculturist*, New York, Sept., 1888.

Copyright, 1888, By Peter Henderson & Co.

among a patch of tall limas. He saved the seed from it, knowing nothing of its value except that he saw that for his own convenience it could be grown without poles. The second season he had quite a patch of it, and gave some to his neighbors, until it ultimately found its way into the hands of a seedsman, who purchased the entire stock. Had the colored citizen only known the prize he had struck, and increased the stock, one acre of this new lima bean would have given him money enough to purchase a good-sized Virginia farm.

You see, friends, it was a sport, just like my white Boston Market lettuce.

Henderson states in his new catalogue that it does not run at all, grows about 18 inches high, produces enormous crops, of

The new Bush Lima bean is the greatest acquisition to the vegetable garden attained in this century. Growing exactly like the common String or Bush bean, its simple culture is identical. It will find a place in thousands of gardens where the old climbing bean is unknown, as not one cultivator in one hundred can go to the trouble and expense of the poles for the old Lima. In the Bush Lima we have not only a vegetable of the easiest culture, with a flavor equaling, if not surpassing, the pole Lima, but above all a bean giving as heavy a crop, and beginning two weeks earlier.—PETER B. MEAD, Mamaronck, Westchester Co., N. Y.

FROM THE LARGEST GROWERS OF BEANS IN THE WORLD.

Your Bush Lima bean, which we have tested very thoroughly this season, is a most valuable variety. It is strictly a bush bean, growing from 15 to 18 inches high, with no tendency to climb; makes a wonderful profusion of pods, some single plants containing 100 good pods, and the majority averaging from 50 to 75 pods per plant with ordinary field culture. The cooking qualities are unexcelled, if indeed they are equaled by the Pole Limas. We think this bean is destined to become the most popular variety in the entire list.—N. B. KEENEY & SON, LeRoy, N. Y.

FLOATING APIARIES IN EGYPT.

HOW THE BUSINESS WAS PROSECUTED OVER 100 YEARS AGO ON THE NILE.

THE following sketch we copy from the *Deutsche Illustrierte Bienen Zeitung* for November, page 44. The engraving also from the same source we reproduce. The article was written by Mr. T. Kellen, of Luxemburg. W. P. Root, our proof-reader, translates as follows:

Not long ago I discovered in the city library of this place, Luxemburg, a French work on bees, which for a century had been unremoved, leaves uncut, and was covered with venerable dust and finger-marks. In this work I found a very interesting notice in reference to portable apiaries of that period. The author of the above work, B. E. Manuël, procured some notes of a description of Egypt, and added a few concluding observations of Reaumur thereto. From this and other histories of travels, as well as from Maillet's Description of Egypt, published in 1740, it appears that, in the last century, there were a great many colonies of bees kept in the land of the Pharaohs, and that a very lively business was maintained therein, quite unlike what we have in our own country. Dr. Westhau reports, in a description of a travel through Egypt, in 1702, the following: "In many places I found apiculture greatly hindered, notwithstanding the inhabitants manifest much interest in it. In the season of bloom they move with their bees, now here and now there, in order to fill their hives with honey."

In the last century there was found, with all of the ignorance and wildness of the inhabitants, an occasional trace to remind one of the previous luxury of a keen and diligent generation, long past. One of the most noticeable evidences of their activity was the annual sending of their bees to remote districts, that they might secure pasturage, which occasionally failed them at their own stands.

As Upper Egypt is hotter than Lower Egypt, and the land there is freer from the inundations of the Nile, the honey-plants there develop at least six weeks earlier. The inhabitants were fully aware of this fact, and availed themselves of it for the benefit of their bees. In Lower and Middle Egypt they placed a certain number of colonies of bees, which were often kept in jugs and bowls, and often in cylinders or baskets made of burnt clay, or made out of withes braided, and besmeared with Nile slime, made expressly for this purpose—forerunners of the portable bee-hives of Swabia. If the hives were required at the upper end of Egypt, they were transported thither, so the bees could visit the neighboring honey-plants and shrubs. When the crop in Upper Egypt was exhausted, they floated the skiffs a few miles down stream, and waited there as long as honey could be found in paying quantities.

At the beginning of the month of February they arrived at Lower Egypt, where they delivered the hives back to their owners. The latter then sold the entire product at wholesale in Cairo. The bee-

keepers from Upper Egypt, after they had disposed of their products in the region of the delta of the Nile, and had secured what honey they could there, returned again up stream to their homes. Unfortunately, hitherto history has furnished us no details in regard to portable apiaries in this land of early antiquity, which are authentic; nevertheless, it is easy to conjecture that that inventive people, as the valley of the Nile bears them witness, will convert it, as they did a century ago, into the business of portable apiculture. One may easily believe that Egypt first suggested the same business to Greece and other lands. The Roman agricultural writer, Columella, writes (*De Re Rustica*), Book IX., chapter 14, in replying to Celsus, that in Achaia the bees from Attica and Eubœa, on all the Cycladian islands to the island of Skiros, and from the various Sicilian coasts to Hybla, were cultivated for honey. This custom was, in all probability, introduced from Egypt at the time of Solon, for the civilization of Egypt is unquestionably much older than that of Greece. Before Solon arose as reformer in Athens he traveled through Egypt, and learned there how to make many im-

A FLOATING APIARY, AS THEY USED TO DO IT ON THE NILE.

provements which he afterward made useful to his native land.

But how stands bee culture now in Egypt? When even the fellahin and Copts conspire to drive out apiculture, no more will be read in modern histories of travels in Egypt in regard to movable apiaries; and no traveler will see any more the skiffs on the Nile, laden with hives. This is easy to be seen, when one reflects how downtrodden Egypt is under the foot of the Mohammedan.

I am sorry that the original manuscript did not give us more particulars. For instance, did that chap in the back of the boat have nothing to do but smoke his pipe? Were the bees fastened in the hives during the trip, or did they work along the shores and "catch up"? Will eight hives of bees, as shown in the cut, pay the expenses of the whole establishment, with two men to run it, letting one man smoke most of the time "to boot"? If the bees are of the *Egyptian* "denomination," I should think the house in the stern might come quite handy.

S. I. FREEBORN'S REPORT FOR 1888.

ALMOST 120 LBS. PER COLONY, AND AN INCREASE OF FROM 265 TO 349.

As requested, I hand you my report, also some items of our work and success for 1888.

I put in winter quarters, in the fall of 1887, 300 colonies—115 at the home yard, and 185 at Sextonville. They were wintered in two underground caves, or bee-cellars, 12x24, made with double doors, and covered with three feet of earth, with sub-earth ventilators at the bottom, and a boxed pipe running out at the top for upward ventilation. The one at home has a brick chimney, with a stove ready to fire up should circumstances require; but no fire was built when the bees were in, as it never went lower than 42°, and frequently reached 46° above. The hives were ventilated, mostly at the bottom, by raising them one inch in front of the bottom-board, except the lower tier, which was raised one inch all around.

They wintered fairly well. Most loss was from the death of queens or from starvation. I lost some by being deceived in the weight of the hives, there being a great amount of pollen capped over with the honey. There was so much that the hives were quite heavy after the bees and honey were all out. I commenced taking out bees Apr. 11th; finished Apr. 14th. The spring was very unfavorable, and we did more feeding than ever before, in one season. We fed inside of the hives while the weather was cool, to prevent starvation. Afterward we fed in the open air when warm enough to be safe to do so, to promote brood-rearing, and we kept it up far into June, until clover bloomed. So unfavorable was the spring that there were few if any more bees when clover bloomed than when first taken out of the cellar. From all causes, we lost, up to June 1st, 35 colonies, leaving us at home 100; at Sextonville, 165 colonies. Our outfit for the season was 265 colonies; 200 supers, or hives, of empty comb; 75 empty hives; 200 pounds of wax; 2 extractors; 10 200-pound barrels left over, and 50 more engaged, with two young men to help—one from Canada, with some experience, the other only one year from Norway, 18 years old, without experience, but very anxious to get some, and he *got it*, too, he thinks. These were my outfit to run for extracted honey for 1888. From the outlook I thought the above sufficient, especially as white clover was badly killed with us, and it was the off year for basswood. White clover amounted to but little in the way of surplus; but with the aid of sumac, lion's-heart, and other sources, bees were in fair condition for basswood harvest, which commenced about July 12th and lasted 16 days.

Our 165 colonies at Sextonville are near the timber, and were not moved during the season. The home lot had to fly about four miles to get to much basswood. We moved 35 into the timber, and intended to move the rest; but the roads were so exceedingly rough at the time, that we gave it up. Those that we moved did finely, gathering much faster than those at home, thus showing that, though bees will carry honey from four to six miles, they can gather it much faster nearer home.

During the 16 days of basswood harvest we realized how fully employed 265 colonies could keep three or four men when they fairly got on a rampage. They worked and swarmed with a vengeance; and had we used all of our surplus hives

and combs we could soon have had them filled with young swarms. I think about 1000 would have been their capacity if we had let them have their will in the matter; but by fooling them every way we could, we had only 353 at the end of the season.

Our surplus of basswood honey was 18,000 pounds. After basswood we moved the 35 that we moved to timber and 76 left at home, 18 miles, to work on mint or any thing else they pleased to get.

The moving of these bees proved to be the most disastrous of any of my experiences. The night the first lot was ready to go was the hottest night of the season; and for the first time in my experience, being unable to attend to it personally, I was obliged to see the boys start with 3 loads (35 swarms), without me. The result showed that I had good reason for apprehension, for they had the luck to kill 16 colonies. We moved the rest, and had 90 left out of the 106. They made about 7000 pounds of mint honey in the three weeks that it lasted. The mint proves to be a fine honey-producing plant; it stands drought like a salamander, and rain affects it but little. It seems to me that it might be the most promising plant to raise for honey of any thing in my knowledge, especially where the ground is sandy.

The Sextonville lot were about 5 miles from the Wisconsin River, but they carried considerable mint honey that distance. It was somewhat mixed with fall honey. We took from them 6000 pounds more, which makes our crop 31,000 pounds of extracted honey, and 600 lbs. of comb honey. With better preparation I could have done better, as I could have used with profit more foundation. I had about 60 hives of full drawn-out comb, but I could not stop extracting to prepare more. I am glad and thankful to get the crop that I did.

My profit comes from the sale of honey, as I sell no queens or supplies. To get this 31,600 pounds of honey cost a great amount of work with teams, men, and brains. I don't see how cripples or lazy folks could handle them if they did it the way we did. Our 349 colonies are in the cellars before mentioned; 130 at home, 219 at Sextonville: one queenless, and I sold 3 swarms.

S. I. FREEBORN.

Ithaca, Wis., Dec. 20, 1888.

Friend F., the above is indeed refreshing. Ernest remarks that it sounds like old times instead of like a report for the season of 1888. Now, besides your yield of honey, you have given us some very important facts which need a little emphasis. One is, that it does pay to have bees as well as every thing else close to their work. The bees that had to fly about four miles did something, but not very much. The 35 colonies that were moved, at once gathered honey much faster than those left at home. I suppose the great secret of your success is the immense basswood forests you have written us about before. If you have a good season next year, if you will send me a telegram at its highest I will try to go up and report for the readers of GLEANINGS. In regard to the mint mentioned in the above letter, I will explain to our readers that friend F. has sent us a sample of the honey, and a package of the plants, with the accompanying letter:

We send you a sample of mint honey, or, as some call it, "bergamot," which to our taste is preferable to the famous white-sage honey of California.

One peculiarity of it is, that it will scarcely granulate. Having had it all winter in unsealed combs, without any visible granulation, we also consider it an excellent honey for winter stores. We also enclose a sample of the plant itself from which the honey was obtained.

S. I. FREEBORN.

Ithaca, Wis., Dec. 19, 1888.

The honey sent us is so thick that it will hardly run when the dish containing it is turned over. As mentioned above, it shows no sign of granulation whatever, although it has been left out in the cold for a week or two. The quality is excellent, with the exception of a little flavor of fall flowers. In 1878, Mr. H. Stewart, of Orion, Wis., from the same county that Mr. Freeborn lives in, sent us a sample of the mint. Prof. Beal pronounced it *Monarda Bradburiana*. It is nearly related to the horsemint of Texas. The plant also grows in our own locality, and it is called around here balm, or wild bergamot. Perhaps it is better known under the name of wild bergamot than any other. Without question, it will pay beekeepers to look up patches of this wild bergamot, and locate hives near them during the proper season. I believe it is found along the low grounds of the Mississippi River, in many different places.

PACKING COMB HONEY FOR SHIPMENT.

SUGGESTIONS FROM WM. MUTH-RASMUSSEN.

WHERE wood is employed, I suppose that great accuracy can never be attained, on account of the unavoidable shrinking and swelling. Yet, the nearer we come to accuracy in getting out material, the less will the subsequent work be. This is particularly noticeable in packing comb honey. A slight variation from a fixed measure may seem a trifling matter in the width of a single section; but when 6 sections are placed side by side it makes quite a difference. I use packing-cases holding 48 sections, and without glass. This style suits my trade. I have had sections which were so wide that they would not go down into their place in the packing-case, and had to be whittled on the edge; yet their extra width was not sufficient to attract my attention when they were folded, but was only too apparent when it came to packing them for shipment. As a rule, however, there is a little room to spare in the packing-case, varying all the way from a hair's breadth to a quarter of an inch. To prevent the sections from moving, I crowd them all up against one side of the case, and then stuff a wad down between the opposite side and the section. This wad, a little shorter than the inside length of the case, is made by loosely folding a newspaper until it is thick enough to require considerable crowding to get it down into its place, and, being loosely folded, it will have elasticity sufficient to keep the sections steady. The projecting end folds over on top of the sections, and serves to withdraw the wad before the sections are lifted out of the case. I do not know of any other way of keying up the sections; but if other comb-honey producers have something different or superior for this purpose, I should be pleased to have them describe and illustrate their methods in GLEANINGS.

To get at something better, if possible, is my principal object in writing this.

WM. MUTH-RASMUSSEN.

Independence, Inyo Co., Cal., Jan. 7, 1889.

Friend M., it is true that a slight variation in measurement sometimes makes a great deal of trouble, and it behooves us all to have our sections and every thing else accurately made. Your wad made of folded newspaper is a tiptop idea; and until somebody else suggests something better or neater, I think we should do well to adopt it.

PREDACEOUS BUGS.

PROF. COOK DESCRIBES THE BUGS THAT MUST NOT BE STEPPED ON.

IN GLEANINGS of Nov. 15th, I described the wheel-bug, *Prionidus cristatus*. I now send an excellent figure of this interesting insect, which is a common one in our Southern States. The female of this wheel-bug (Fig. 1) lays in a group about seventy eggs. These are bottle-shaped, and

FIG. 1. PRIONIDUS CRISTATUS.

appear as would many bottles standing side by side. The young only, resemble the mature insect in form and habit. They are blood-red, and, like the adult, pierce and suck the life from scores of injurious species.

I wish now to call attention to another bug, the soldier-bug, *Podisus (Arma) Spinosus*, Fig. 2. This has a short sunken head, and so reminds us of our injurious species like the black squash-bug, the terrible chinch bug, and the destructive tarnished plant-bug which is sometimes so fatal to the strawberry and almost every year to many of our garden vegetables. Thus this soldier-bug, one of our valued friends, closely resembles in form several of our most dreaded pests. Yet the beak is stronger, while in the plant-destroyers the beak is slim, as will be seen by the FIG. 2. SOLDIER-BUG. figure, where the beak of the squash-bug is shown with that of the soldier-bug.

The spined soldier-bug is a gray lavender or brownish yellow in color. The specific name comes from the sharp spines on the side of the thorax. The figure is magnified twice, as is also the wheel-bug in Fig. 1.

In pinning all insects, except beetles and bugs, the pin is passed centrally through the thorax. In pinning bugs we always pin through the little triangle (Fig. 2), technically known as the scutellum, of the meso-thorax. In another article I will show how to pin beetles.

The spined soldier-bug is one of our most important predaceous insects. I have seen it dining on the grubs of our common potato-beetles, and its appetite is not easily satisfied; on the large fine tent caterpillars, and on several others of our most dreaded insect-pests. Thus in the future, when we elevate our noses in contemptuous derision of all bugs, let us bear in mind that some of them, notably the wheel-bug and spined soldier-bug, are our good friends, even fighting to rid us of our foes.

Agricultural College, Mich.

A. J. COOK.

CALIFORNIA.

ITS WONDERFUL CAPABILITIES, AND ESPECIALLY THE DIFFERENT RESULTS OBTAINED IN LOCALITIES BUT A SHORT DISTANCE FROM EACH OTHER.

FRIEND ROOT:—Your travels in California are quite pleasant reading; but, like all those who have not spent years here in various parts of the State, you generalize from particular instances much too freely. For instance, you say (p. 975), "A little neglect in irrigation, and your strawberries, corn, aye, and even orange-trees, are 'gone dead,'" and several other remarks of a like kind; yet at my place (near Santa Paula) I could have shown you tons of fine corn which never had one drop of water, from planting to husking—either rain or irrigation. My ranch is without water except what I catch in tanks and cisterns. I can show you dozens of thrifty oranges, lemons, pomelos, and other citrus trees that had half a pail of water each when set out, and no more, except the natural rainfall. We have tomatoes every day in the year, without irrigation. Fig-cuttings planted two years ago are now large bearing trees, a foot in circumference. I have now growing, since 1884, when I homesteaded my place, the following fruits: Apples, pears, olives, quinces, apricots, almonds, walnuts, figs, nectarines, prunes, plums, cherries, guavas, persimmons, and other Japanese fruits, oranges, lemons, loquates, pomegranates, pomelos, besides small fruits, grapes, and some rare kinds like *hovenia dulcis*, *zapote blanca*, etc., and all these are grown without irrigation, almost at the top of a mountain. The secret lies in thorough cultivation. Yet, as a *paying crop*, I should never think of planting strawberries, for example, though I could make them grow and bear some, almost any time of the year.

The truth is, one never knows what will do well on a piece of ground until he tries it. Nor can you be sure of varieties paying in untried localities. For example, take my nectarines. In 1884 I planted Hardwick, New White, and Boston nectarines. In 1887, the Hardwick bore 150 lbs. to the tree. The others bore not one. In 1888, the Hardwick bore 175 lbs. to the tree. The others bore a dozen pounds. My peach-trees varied from 425 lbs. to 20. My apricot-trees showed me that the Royal and Hems Kirk here bore almost ten times as much to the tree (about 200 lbs.) as the Moorpark and Peach apricot; yet 6 miles away the latter kinds are the choice varieties. One mile east of me apricots do little or nothing, while pears are a success. My pears are a failure. I planted 150 trees in 1884, and have got a dozen pears so far. So I might go on through the lists of fruits, but one more example

will suffice. In one part of my cañon, near the house, I have three English walnuts, not two years old, from the nut, all over 9 feet high, and one over 11 feet, an almost unparalleled growth. Not far away I have three others in like good soil, having had like care, and they are not three feet high. Why this difference? The former had more rain three or four times during the two winters. In fact, they had what was equal to double the rain of the others, owing to their situation at the foot of a hill. I have 12 acres in English walnuts, all growing very well indeed, yet I shall not know whether walnuts pay in my cañon for eight or ten years. I simply *guess* they will pay. Soil, rainfall, shelter, location, all have a wonderful influence.

Now about the chicken business, which looks so profitable here to you. True, we can raise lots of chickens every month in the year, and *vermin too*. My next neighbor, last year, with 19 hens, raised over 200 chicks with little care. But next month she may have 19 left. One friendly cat (*lynx*) reduced my stock by dozens in a few days. I wake at night and hear the chickens crying "badger!" and see three or four dead in the hen-house. A sportive cayote gobbles up a wilful hen and her chicks from their nest—hid from my eyes. A fat squirrel runs for the egg when he hears a hen cackle, and finds the egg half way down a gopher-snake's neck. We have nearly as many hawks here as chickens, and—we generally have enough eggs to use, and we eat at least half as many chickens as the "varmints" get, so it pays us to keep chickens, though I believe bees pay better.

Now a few words about our California names, which are often very suggestive. The "Chollas" (pronounced Chó-yá) Valley was named from a kind of cactus. Spanish double *l* is pronounced like "y" by our Mexicans.* "Tia Juana," meaning "Aunt Jane," is really a corruption of an Indian name meaning "by the sea." Omitting the saints, more than half those odd names are really Indian, and more than half the Indian names have "water" as a part of the word. Now, why so many saints in California? The early Spaniards were very religious. They have one or more saints for every day in the year. They discovered San Diego on St. James' day, and San Dieguito on the day of the Lesser St. James. If they camped at San Luis Obispo on the day of St. Louis the Bishop, that was the name to give the place. Another day it was St. Luis Rey (the King); another, the day of the Queen of the Angels (Los Angeles); another, San José (St. Joseph). Both Indians and Spanish were extremely unimaginative in most of their namings. Valle de las Viejas (ve-a-has) sounds very poetical, but it is simply "the valley of the old woman;" that is, where an old woman lived. Arroyo Burro is the creek where some one lost his donkey. They get imaginative only when they get scared. Thus, friend Wilkin's bees are at the mouth of Sespe Creek, and the Sespe are devils which they thought lived in those oil-springs and spoiled the water. Further up is a "Devil's Potrero," or pasture-ground. I made California names a special study for some time, so if those who are reading up the State want to inquire about meanings or pronunciations I am "loaded up."

*The Spanish *ll* should be followed by *y*; hence "Chollas" should be pronounced "Choa-l-yas." In Spanish, *ch* is like *ch* in the English word *chair*.

Now about how to plant your orchard (query on page 980). Make an equilateral triangle of straight slats, whose sides equal the distance you want your

trees. Suppose A B, A C, and B C, to be each 20 feet. Drive your pegs at each intersection, holding the triangle level. Then by moving it $\frac{1}{2}$ around you get one new stake, and so on throughout the orchard ground. That divides the whole field into exact equilateral triangles staked out. Now you dig a hole and put your frame against two stakes, and put the tree in the third corner. It will thus come just where the stake was. In that way your trees are in line in every direction, as you can see by matching your equilateral triangles together on a stake, marking the corners with a dot. This is called the quincunx method, though erroneously, since they are not squares with a center tree, but rhombs. That does well where you have all one kind of trees, but walnuts should be 50 feet apart; oranges 30; almonds 25; prunes 20, while some plums, persimmons, etc., are as good 12 or 15 feet. With the variety I have, I am quite satisfied if they range two ways, so I can cross-cultivate. The other does look nice, but it hardly pays with mixed fruits. I was sorry the weather prevented my meeting you in Santa Paula.

C. M. DRAKE.

Springville, Ventura Co., Cal., Jan. 2, 1889.

Friend D., I am exceedingly obliged to you, and your letter makes me feel sorry that I didn't take time to make you a visit. When I take that next trip, you may be sure I shall take in your ranch. I am aware that there are a few localities in California where things do not die, even if irrigation is neglected. I believe I spoke of the corn-fields near Santa Paula; but I supposed the corn was planted before the spring rains were entirely over. In riding along, I was continually asking questions about what kind of trees would live without irrigation, and what would not. Perhaps I have forgotten by this time; but I believe that apricots and walnut-trees in most localities require no irrigation at all, after they are well started. I believe I mentioned that the eucalyptus grows almost anywhere, no matter whether it is wet or dry, if it once gets a little start. The point you make, that "no one knows what will do well on a piece of ground until he tries it," is true with us here in Ohio; but it is more especially true in California. The difference in the changes from mountain to valley, from sand to 'dobe, from one exposure to another, near the seacoast or remote from it, and ever so many other things taken all together, makes the matter of gardening and fruit-raising quite complicated. I believe if I were you I would try one tree of a kind, then gradually increase the number of those that do well; and the same sort of reasoning here will apply to good advantage. The objection with fruit and nut bearing trees is, that it takes so much time; but while the years are passing, we can do it oftentimes as well as not to do it; and if we never live to see the result worked out, our children probably will, and be benefited by

it.—Friend D., with all the advantages you have for the chicken-business, I would make a vermin-proof fence for the fowls, and then I would fight the vermin with traps, poison, clubs, dogs, and cats; and, in fact, our successful men here have to do a good deal of this kind of work.—The matter of California names is one of great interest to me, but it may not be profitable to devote too much space to it.—Great numbers of devices have been sent in to us for planting trees in regular order; but I think your triangle about fills the bill. It is the very thing we used in shaping our hexagonal apiary here at the Home of the Honey-Bees; but for locating the different apiaries, we had an immense triangle. Instead of planting the grapevines in corners, as you have it, we bored a hole through both pieces of board that formed the triangle, and then put in an iron stake. If your iron stake has a ring in it at the top, large enough to slip your hand in, the opening in the ring being made about like the bow in a common door-key, you can force stakes into the ground, and pull them out much more easily. I think I would stretch a line to one side of the orchard, in commencing; then with the aid of the triangle and the iron stakes we can, providing it is on level ground, make the trees come straight, to a dot. The device illustrated in another column will help to get the trees planted exactly where they should stand. I noticed in California many orange-orchards laid out on this plan. Then the harrow was passed through in three different directions, leaving only a little triangular spot around each tree to be fined up with a steel garden-rake. I think I never saw ground worked so handsomely as were many of the California orange-orchards. I fairly ached to get out of the buggy and get hold of a rake, and help do the finishing-up around the trees. Most of the ground was of a kind that does not easily pack, as our ground packs when the horses walk over it. We, however, are often troubled by being obliged to work the ground when it is a little too wet. Where irrigation is practiced, of course this never happens.

NOTES FROM THE KEYSTONE BEE-FARM.

PEDDLING HONEY, ETC.

I MUST tell a little of my experience in peddling honey. I took a load to Wilkes-Barre, just before Christmas. I first offered it to the commission merchants. I found they were well supplied, and were selling basswood honey in one-pound sections at 13 $\frac{1}{2}$ cents by the case. I next called on the leading grocer, Wm. M. Miller. He wanted honey, and I had a first-class article, but he thought it was too cold a day for me to get 16 cents, which was my price. I then concluded to peddle out my load. I supplied nearly all the hotels and some private families. I am acquainted with nearly all the court-house officials and lawyers, and made many good sales among them. I called on my old comrade, Major G. R. Lennard, with whom I served four years during the war. I sold him some fine clover honey at 18 cts., but he

was inquisitive to know whether it was not the *new process* honey, as it was so nice. He said that undoubtedly much of the comb honey on the markets was machine-made. I gave him the address of A. I. Root, and told him that he had a standing offer of \$1000 for a sample of artificial comb honey.

THE LANGSTROTH VERSUS THE AMERICAN FOR WINTERING.

O. O. Poppleton, in the *Dec. Review*, says that it was never claimed that bees would winter better on a shallow than a deep frame. Our bees are on American and Langstroth frames, in chaff hives. We winter on seven frames, and last spring it was a noticeable fact that those on American frames (28 in number) were nearly out of stores, and some had to be fed, while those on the L. frames had clustered in the fall on the ends of the frames next to the entrance, and on May 1st had reached only the middle of the frames, and had nearly half of their stores still on hand.

THE SIMPSON HONEY-PLANT.

The Simpson honey-plant (figwort) is quite plentiful in this section. Last season I cultivated some plants for our bees; but during the whole season not a bee touched it, showing conclusively that location has much to do with the honey-producing qualities of plants.

Our winter thus far has been a favorable one for the bees. Our coldest weather, 16° F., was on Dec. 22, and since that time it has been beautiful Indian summer, the bees flying almost daily.

S. W. TAYLOR.

Harveyville, Luzerne Co., Pa., Jan. 7, 1889.

THE SEED CATALOGUES OF THE PRESENT AGE, ETC.

ALSO SOMETHING ABOUT ECONOMIZING EXPRESS CHARGES.

IT is indeed a treat to any one who loves gardening, to look over the beautiful catalogues that are now sent out yearly in the months of January and February. It gives one a glimpse of the progress that is being made, and also of the immense business done in just this little matter of requisites for the garden. When visiting Matthew Crawford last fall, while he was busy with a customer I began to look curiously at some little plats of various kinds of vegetables. They were well cared for; and the wonderful crops in these little patches excited my curiosity. When I asked for an explanation, friend C. spoke something like this:

"Mr. Root, when I get a bright new catalogue that evidently cost the seed-grower quite a little sum of money *apiece*, I have always had a sort of feeling that he deserved at least a little encouragement from every one who received it; therefore I mail a little order for onion seeds to our friend Maule; buy some new wax beans of Burpee; a few packets of Henderson, and so on; and if I get the seeds, of course I must give them a little plat of ground. These great red onions that you are admiring here were

the product of Maule's strain of Wonderful Red; these great white ones are Burpee's Silver King, and so on. I have no particular use for them, growing strawberries mainly, as I do; but it gives me a feeling of pleasure, just as it does you, in this: That these new things are really what they are represented to be, and that they are certainly superior to the common kind we have been selling."

THE NEW SYSTEM OF PACKING.

Now, the above may not have been exactly friend C.'s words, but they are the sum and substance of them, and I do think that every one of you who receives one of these beautiful illustrated catalogues, with their colored plates, ought to send the proprietor at least a small order for seeds, by way of encouragement. If you pay 10 or 25 cts. for the catalogue, you need not make an order unless you choose; but where it is sent you free, I think you can pick out at least a few simple things that will be worth all they cost you, and at the same time prove an encouragement to the one who expends so much money in getting up the catalogue.

But I started out to talk about a new cheap packing for sending seeds, plants, etc., by express. We found it figured in Henderson's new catalogue of the present year. The cut explains it.

You will notice, friends, that it is simply a common market basket, without a handle. Over the top is a piece of oil cloth, hemmed around the edge so as to permit running in a sort of puckering-string, to draw it up securely under the topmost hoop of the basket; and for additional safety, two stout cords are put around the whole, to which is hooked a handle to carry it by. The whole apparatus weighs only a pound, and it will carry a lot of seeds, plants, bulbs, or any thing else, just as safely as a great heavy box that weighs 10 or 15 pounds; and who has not paid a big lot of express charges on a heavy box when the box was not needed at all? Why, hundreds of our patrons send us beeswax in great heavy boxes, when a light cloth bag would answer every purpose in the world. Now, I do not think beeswax should ever be sent by express at all. It may be, however, where you are short of money, and have the wax, and want some foundation by express, you decide to do it; but if so, do not, I beg of you, put it in a box.

Tie it in a stout bag, and we do not care how much it gets pounded up before it reaches us. It is not an uncommon thing for us to receive wax by express when all of the wax would hardly pay the express charges. For some years back we have been much in the habit of using baskets similar to the above, for shipping things by express; and this present season we are going to do it still more. Half-peck baskets we frequently use for sending things by mail. A basket will really stand more banging around than a box; and a great many times it will preserve the contents from injury just as well as or better than a box. The moral to all this is, that, when you have any thing to send by express, be careful not to have the package weigh a single pound more than is absolutely necessary for the safety of the goods.

BEE-KEEPING FOR WOMEN.

BEVELED-EDGE HIVES; TAKING OFF HONEY, ETC.

I HAVE about come to the conclusion that all this moaning and groaning about bee-hives being heavy to lift, and about bee-keeping being too hard work for women, is unnecessary and uncalled for. If all the women who keep bees will manage as Mrs. L. Harrison has always managed, and as I intend to manage from this time forth, they will not find bee-keeping such very hard work.

The next day after I came home from Peoria I went to work to prepare the bees for winter. Last spring I had nine colonies. Now I have twelve. I had seven swarms to come out. Four of them went to the woods, leaving the queen under a goblet on a plate. Two of the four swarmed, and, before I could do any thing, they went back into the hive. The next time, they came out and went off without settling at all. The other two hovered around the barberry bushes awhile, began to cluster, then flew away. I did not want any swarms. I thought there would be no honey, and that they would have to starve. I had a good many old combs and I put them all on the hives, three deep in some places. It was the easiest way to keep the moth out, and I thought now was the time to prove whether giving plenty of room would prevent swarming. I am now convinced that nothing will prevent swarming. If bees want to swarm, they will swarm. It does not depend on a honey-flow. Some of those colonies had not three days' rations ahead. It does not depend on any thing—they just swarm.

Well, they went on in a hand-to-mouth way till toward the last of July; then the rains came, and the oats rotted in the field—three hundred dollars' worth. We never thrashed a straw. (This is the price that I am obliged to pay for my 300 lbs. of honey. Let me see: that makes my honey worth about a dollar a pound, does it not?) The smart-weed began to bloom, and the bees began to roar. They filled all those old combs, and the honey-boxes; and when I went out there to take that honey off, I found I could not budge it. I had a chisel and a hatchet, and I pounded and pried here and there, but could not move it an inch. You see, all that time while there was no honey to gather, the bees had put in their spare moments plastering those hives together with propolis. I worked till I

was hot and tired, then I thought, "What is the use to be a married woman, if I have to work just like a widow?" and so I went to where Mr. Chaddock

"I POUNDED AND PRIED."

was unloading apples and carrying them into the cellar, and told him that I must have help. He

"MUST HAVE HELP."

donned a bee-hat, and worked the chisel and hatchet while I stood by and worked the smoker and

"HE WORKED THE HATCHET AND I GAVE ADVICE." gave advice. After he had worked awhile at one, and torn off a side, he began giving his opinion of a man that would invent such a bee-hive as that.

But I stopped him, by telling him that that was the bee-hive that Mr. Root invented on purpose for ladies, invalids, and preachers to keep bees in, because it was so light and handy.

GIVING HIS OPINION.

Well, he pried all that honey loose; took it off and carried it into the house. After he had finished I asked him how much honey he thought he had carried in. He answered instantly. "A thousand pounds."

"Oh, no!" I said; "tell in earnest, so I can write it down."

"Well," said he, "put it four hundred. I know there is that much."

As most of the combs were old ones, I shall say three hundred pounds of honey.

This letter is long enough; but I want to tell how to get bees out of honey-boxes—how to keep moths out of old combs, and something about division-boards, etc. I will end this as I began, by saying that bee-keeping is not very hard work, and every woman might as well keep bees as not.

Vermont, Ill.

MAHALA B. CHADDOCK.

Mrs. Chaddock, you are very graphic, but your illustrations bear rather hard on the Simplicity hive. Please say to your good husband, Mr. C., that the Simplicity hive was never intended to be used in the way you describe; that is, we do not intend to have the propolis get into that beveled joint, as it must have done in your case, to make it stick together. When I decided to tier up the hives in order to get the whole product of the season, in stories three or four high, so as to extract all at once, I took particular pains not to let the propolis run down across the bevel, where the hives come together, when placing them one on top of the other; but when the bees put so much along the crack that it was likely to get in the joint, I scraped it out with a putty-knife. In some cases I rubbed tallow along the upper edge. This entirely obviates all the difficulty you experienced. When I find hives where the propolis has been allowed to get down the joints so as to glue them fast, I always choose a day to separate them when the hives or the weather is so warm that the propolis will be in a soft state. If this propolis is allowed to accumulate, and get into the joints, it will make every operation with a bee-hive dauby and disagreeable.

WINTERING BEES.

BEE DIARRHEA THE ONE GREAT CAUSE OF OUR WINTER LOSSES; FRIEND HEDDON EXPLAINS.

YES, friend Root, I can answer for myself, and shall be pleased to do so. I rather like the style of our crisp friend Hamilton (see page 9, Jan. 1st). I will say, for the benefit of Mr.

Hamilton and your readers (if what I have to say will benefit them), that, by a belief in the pollen theory, and manipulation accordingly, I mean I can winter any colony of bees with greater certainty of success, and keep that identical colony (not the identical bees, however) in existence longer than any one can keep a horse or a cow. At our late State convention at Jackson, an overwhelming majority of the members present, and, in fact, I think every one of the older and larger bee-keepers, believed the pollen theory to be correct. I am aware that bees will winter very well in a hive containing much bee-bread, provided they do not eat it, and I know some of the conditions which cause them to eat it or let it alone, but I do not know all of them, but am learning more each year. A low temperature is the greatest of all causes of consumption of bee-bread in confinement. Of course, if it is not in the hive they can not eat it; but, at the same time, the bees can be damaged by too low a temperature, and killed outright by it if it is allowed to go low enough and long enough. Any one who will take a colony of bees, and see to it that they have no pollen in their bodies at the time, and can not get any after the time, and who will take away all their combs and feed them properly prepared sugar syrup in dry, clean combs, and who likewise will place them in a repository, keep the temperature between 45 and 50 degrees, can leave them so six months or more—I do not know how much more; and when he takes them out the bees will be as bright, slim, and healthy, apparently, as when they went in. They will not void a speck of any thing on their first flight.

But now I imagine I hear friend Hamilton ask how my bees have wintered in the past few winters, and why some of them died with bee diarrhea. I will tell him. If honey were worth a cent a pound, and bees about forty cents a colony, would it not be better to take lots of chances and let them die if they will, rather than to go to the trouble of feeding them a cash article, taking from them an article in place of it which has a very slow and uncertain sale indeed? I trust you see the point. Even at the present price of bees and honey, if the best methods of wintering are used I prefer to take my chances rather than extracting honey from the combs and feeding back sugar syrup, or, rather, exchanging combs so as to get rid of all pollen. You know it is a job demanding much labor, and endangering robbing. It is a disagreeable time to work among bees; but with my new hive, however, I can do the work without being annoyed with robbers, and in less than one-fourth the time and one-eighth the labor; and the consequence is, we have almost perfect success with the new hive. We take a little risk; but we could quite readily, and with little increased labor and no increased expense, fix things perfectly safe and sure for wintering. Without occupying valuable space, you will see just how this can be readily accomplished,

providing the pollen theory is correct, as myself and others well know it to be. Hoping I have shed some light which will be received by Bro. Hamilton, I will leave further notes for future articles.

JAMES HEDDON.

Dowagiac, Mich., Jan. 10, 1889.

Friend H., I am not so sure about the pollen, but I am sure that there is a great deal of sound sense in your concluding paragraph. Even if we could save a colony of bees by removing the pollen, or, if you choose, by taking them into the greenhouse and giving them a fly in the middle of the winter, so long as bees can be purchased in the spring as cheaply as they are now offered it would be cheaper to take the chances, as you say. Of course, every prudent bee-keeper will see that his bees have enough to keep them from starving. But while it is by no means certain that the honey they have is going to prove disastrous, I would not throw it out and give them sugar syrup instead. Neither would I fuss to get all the pollen out of their hive, when it is by no means certain that they will not winter very well just as they are.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

SECTIONS BULGING; HIVES BY FOOT POWER VERSUS FACTORY-MADE HIVES.

WILL putting on a whole crate, or from seven to eight wide frames, prevent bulging? or is the only expedient separators?

Which is cheaper—to buy my hives, paying \$1.20 for chaff in flat, 75 cts. for Simplicity, or to buy a Barnes foot-power?

Penrose, Ill., Jan. 3, 1889.

B. F. HOOVER.

Putting on a whole crate of empty sections without separators will discourage, although it will not prevent the bees from bulging the combs. When separators are not used, bulging is caused principally by taking out the completed sections and putting empty ones in their places. The bees are then inclined to bulge those partially filled into the spaces occupied by the empty sections. Separators are the only sure expedient; and while you can dispense with them, most bee-keepers prefer to use them.

It is a little hard to answer your second question, as so much depends upon freight rates, the price you would have to pay for lumber in your locality, and the requisite skill you may have. Generally speaking it is cheaper to buy the hives, if your freight rates are reasonable. The principal expense in a hive is the lumber. The cost of making has been reduced to such a low point it would be a very difficult matter indeed for an inexperienced person with a foot-power buzz-saw, even if his time were not worth much, to make any thing. Where one persists in using odd-sized hives, a Barnes saw, without doubt, would save money. In regard to a foot-power buzz-saw, let us say that it takes lots of hard work; and if one is not used to manual labor he will find himself considerably the worse for wear after running one of these

machines. If you are a good mechanic, and can buy surfaced lumber for less than 3 cts. per square foot if your freight rates are high, and if, too, you are used to manual labor, it would pay you, probably, to buy a Barnes saw and make your hives, providing you have odd spells which you can not devote profitably otherwise. Where hive-making is made a specialty, certain fixed gauges are employed; hence, accuracy and nicety of work is almost the inevitable result.

NAPOLEON, AND HIS MORAL CHARACTER.

I can not allow your remarks, p. 854, regarding Napoleon, to pass unnoticed. The sentiments attributed to him did not influence his life; and if we look at his actions, where can a greater monster be found? I was born, and lived in the earlier part of my life, in the part of England where it was supposed, if he paid us a hostile visit, he would land, and opposite to which he had actually prepared a flat-bottomed flotilla for the purpose of crossing. As to his cruelty, I will give but three instances. First, his directions on the birth of his child, that, if it was necessary to sacrifice either, it was to be the mother. Second, when his sick had become so numerous in Egypt as to become troublesome, his direction to the doctors to poison them. Third, in his retreat from Moscow, after crossing a bridge himself, directing it to be destroyed, regardless of the consequences to his followers. For the sake of my country, I have always regretted that he did not fall into the hands of the Russians. I can not doubt that they would have made short work with him. It was no doubt wrong; but on standing on his grave in the island of St. Helena I felt some satisfaction in knowing the enemy of Europe was under my feet.

W. P. TAYLOR.

Fitzroy Harbor, Ont., Can., Dec. 21, 1888.

Friend T., I am much obliged to you for the facts you give us. I did not intend to convey the idea that Napoleon was himself any thing remotely approaching a follower of Christ; but I am pleased to know that he recognized the true character and mission of Christ Jesus. The Bible tells us that even "the devils believe, and tremble;" but I fear that Napoleon believed without trembling, from the report you give of him.

REPORT OF THE SEASON; THE VALUE OF UNFINISHED SECTIONS.

The past season was here a poor one. My winter losses were heavy, saving only 34 out of 85 colonies in the fall, and 8 of the 34 were very weak. I increased to 53, and took only 650 pounds of honey—550 of extracted, and 100 comb. The latter was secured in trying an experiment to know whether

IT PAYS TO SAVE UNFINISHED SECTIONS OF COMBS.

I selected three colonies of as equal strength and condition as my judgment dictated, and placed on one hive sections of empty combs in crates left over from the previous year. On another hive I placed sections filled with foundation in crates. On the last hive I placed sections with foundation starters only, also in crates, adopting the tiering-up plan. Now for the result: From the hive with the unfinished sections, I took 56 sections weighing 63 pounds, and took the first premium at our county fair, on case of 12 best-filled sections of honey

(with three competitors). From the hive with sections filled with foundation I took 24 pounds, a part of which were poorly filled. From the hive with starters only, I took 13 lbs. I used the $4\frac{3}{4} \times 4\frac{3}{4} \times 1\frac{1}{2}$ section. A season with a good flow of nectar, the result might have been different.

Thanks for the biographies of our leading bee-keepers. ELIAS COLE.

Ashley, O., Jan. 10, 1889.

Friend C., your report is very valuable, but I am sorry to say that you omitted in your experiments one of the most valuable, or, perhaps I might say, *vital* points. No one claims, I believe, that the bees will fill a case sooner when *entirely* supplied with new sections containing foundation. Every crate of this kind should have one or two sections, with comb partly built out, to induce the bees to make a starting. Now, had you prepared the case in this way, my opinion is that it would have given more honey than the one where the crate was made up entirely of partly finished sections from the previous year. Will somebody else please give us reports in regard to this matter, especially tests made as I have stated it?

MATING OF THE QUEEN AND DRONE ON THE WING. AS SEEN BY AN EYE-WITNESS.

I have your A B C book before me, open at page 72—"Mating of the Queens and Drones." On June 21, 1888, I saw this mating take place. The queen issued from the hive, took two circles, and came within five feet of my face, and was there met by a drone. They seemed to face each other, clinging by their fore legs, their bodies being perpendicular, and in this shape flew from my sight. It happened so unexpectedly that I hardly knew what was going on before it was too late to follow them. I could have easily kept up with them. I have described this because your book says they have not been seen, only as they were whirling about each other. I saw these fasten; and as they did so they turned and came together, square up and down; and as they flew away their bodies inclined about like this /, and each bee was using its wings. I now would ask you bee-men of experience if you would call this a mating. Have any had the opportunity of seeing the same?

Myrtle, Pa., Jan. 2, 1889.

E. A. PRATT.

Friend P., we have had accounts already, similar to yours, but I believe that, in most cases, they speak of insects whirling one about another, which you do not mention. The point yet undecided, if I am correct, is, to witness the whole operation until the queen releases herself and leaves the drone to drop to the ground dead, or, if both fall to the ground, the separation of the queen and going back to the hive. The meeting has been described at least several times, much as you describe it; and by standing at the hive, the queen has been seen to come home with the usual appendage attached to her, so that we know pretty nearly all about it. It is quite likely that they do not behave, at all times and under all circumstances, exactly in the same way. At the time when so many were experimenting, with the view of being able to bring about this meeting by artificial means, the subject assumed the shape of a good deal of practi-

cal interest; but since the matter of artificial fertilization has been mostly dropped as impracticable, by universal consent, there is also less inquiry in regard to it.

DR. MILLER'S BEE-ESCAPE; TAKING OFF FALL HONEY.

As soon as we read of Dr. Miller's miniature tents we made three; but we did not find their use necessary for fall. One morning when we found the bees all out of the supers and down on the brood-combs we took off the supers. Altogether there were four of us—two to open and take off supers, one to carry in the supers, and one to put on a quilt and the hive-cover. We ran through them so quickly that we needed no smoke, and we had the hive covered before they woke up. In that way we went through the whole apiary very quickly.

Roseville, Ill.

MRS. L. C. AXTELL.

Mrs. A., you do not explain enough. Do you mean that the cool frosty weather drove the bees down out of the supers, and that you took advantage of this state of affairs, and got the honey off without any need of driving the bees out of the sections? I have sometimes succeeded in doing this; but the snapping of the supers when they come off will ordinarily start the bees out unless we work very rapidly. As the engraving came in the issue for Sept. 15, it was probably October before you got to taking the honey off.

OUT FOR A FLY; SOME STATEMENTS REVIEWED.

I am out for a fly, and intend alighting wherever I can get anything to pick at. I think Dr. Mason deserves the first "dab." About a year ago he promised he would keep a paternal eye on the bee-journals and bring up sharply all and sundry who deviated from the true line. Either bee-literature has been exceedingly straight from then till now, or he has gone woefully back on his promise. I have not noticed a single instance in which he has brought the erring to task in the meantime. He can hardly plead that every thing which has appeared since can be brought to the plummet and prove truly laid. Surely the doctor's promises are not like pie-crusts—made to be broken?

I should like to gently tickle the ear of Mr. Doolittle with a feather from my wing, if it would correct his mistaken notion of the honey-producing qualities of the hard maple. He says: "We are told nearly every year of bees getting honey from hard maple.*** I have come to the conclusion there was a mistake somewhere." Without doubt the mistake lies with Mr. Doolittle and those who think with him; for a very considerable quantity of honey was gotten from this source in this section during the early part of this season. A neighbor of mine took several hundred pounds of hard-maple honey. Of the source from which it was gathered, there can be no doubt. I suppose nothing short of proof will convince the gentleman of this fact. Fortunately, I am in a position to supply the proof by sending you a sample of the honey, which you may, if you please, transmit to your doubting correspondent. If the *soft* maple flourished to any extent here, it might be said it was from it the honey was gathered; but it does not.

I think I had better now alight on the shoulder of Dr. C. C. Miller, as I see him and his companion bearing toward the cellar-door a well-stored hive,

suspended in his new hive-sling. The doctor is a public-spirited man. He does not hide his light under a bushel, but freely bestows upon his brethren the products of an ingenious mind. "Virtue is its own reward," so is generosity. If the doctor were less generous in imparting to others the fruits of his own researches he would not have the gratification of seeing himself in a wood-cut simply because he has discovered that a rope is a good thing to carry hives to the cellar. I refrain from picking at the rope, out of consideration for the safety of the doctor's toes. R. MCKNIGHT.

Owen Sound, Ont., Can.

NEW ZEALAND, AND THE EARLY SEASON; THE SWARMING-NOTE.

The swarming season commenced in this locality at least three weeks earlier than usual, and the bees were doing well; but for the last two weeks the weather has been terrible—raining, hailing, and blowing a gale every day, and as cold as we have had it through the winter. There is plenty of white clover now, and if the weather holds good I think honey will be plentiful. I grew a good piece of figwort in my orchard, also mignonette, and the bees do well on them every year. On account of late frosts, and the difficulty in getting the seed to grow, the spider plant does not do well every season. I am starting an apiary about five miles from home. It is in a splendid locality, and I hope to get a good yield from them this season.

Masterton, N. Z., Nov. 25, 1888. THOMAS DIXON.

RAISING THE TEMPERATURE IN CELLARS.

In reading your questions and answers in GLEANINGS of Jan. 1st, in regard to ventilation of cellars, a thought struck me that probably would benefit some of the many readers of GLEANINGS. The use of a lamp or a lantern would dispense with the use of stoves in bee-cellars. If you place a lantern in a comparatively closed cellar, free from drafts, you will be surprised to see how rapidly you will gain one or two degrees of temperature; and if you have a room in your house which is subject to dampness, try placing a burning lamp in it in the morning. By bedtime you will have a room fit for any one to sleep in. If any of these suggestions are of any value to the readers, it is returning a kindness, for I am very thankful for the many I have received. The biographical sketches of prominent bee-men was quite a Christmas present. I am reading the editor's Notes by the Way, with delight. PERRY FOCHT.

Uniopolis, O., Jan. 4, 1889.

KEEPING DOWN THE TEMPERATURE IN A WINTER REPOSITORY; IS LIGHT DELETERIOUS OR NOT?

I constructed a small house last fall to winter my bees in. The house is 8½ by 12 inside; the walls contain one foot of sawdust. I placed 42 colonies in it. It proves to be too warm, and the only way I can keep the temperature down is by leaving the door open a little. By so doing I can keep it at 40° about all the time. Now, I wish your opinion as to how much harm will result from the light while the temperature is kept at that point.

Brownstown, Wis., Jan. 14, 1889. H. LATHROP.

Friend L., light is generally considered to be deleterious to the best welfare of colonies in winter repositories, though a very little may do no harm. In your case the question hinges on how much light is admitted into the repository by opening the door a "lit-

tle." You are better able to answer that question for yourself. If, after examination of the colonies, they appear to be doing nicely, and are clean and sweet, then the admission of a little light by opening a door a trifle would do no harm. We would refer you to the Dec. 15th issue of GLEANINGS, in the Question-Box department, for particulars in regard to light in cellars or other repositories.

In addition to what Ernest has written above, permit me to say I do not think it will do any harm in a bee-house or cellar, so long as you keep the temperature down to 40°; but in our locality it would be impossible to do this. This 23d day of January, the thermometer is up nearly to 60°, although the day is cloudy. When this temperature continues for a couple of days or more, we have found it very difficult and even impossible to keep bees quiet in a winter repository, even when kept in darkness.

TURKEY BUZZARDS, CUT-WORMS, AND BEE-VEILS.

I do so appreciate the photographs of Professor Cook and father Langstroth, that the price of GLEANINGS would in no way be sufficient to purchase them. By the way, we have a professor A. J. Cook, of Alabama, and one of the best men I ever knew; and I am bound to think he must be a relative of your A. J. Cook.

You don't know how much I enjoy your description of your journey to California. I was really amused at your scare-crows. What queer notions a Yankee has of things at the South!

In the 15th of June GLEANINGS, page 481, D. W. C. Mathews asks for a preventive of cut-worms. Tell him that, in the spring of the year, when he first commences to break up his ground to sow for a small garden, say ¼ of an acre, a peck of common salt spread evenly over the surface of the ground, and plowed in, is good. For an acre, one bushel of salt is the proportion. If this is done soon enough it will prevent the cut-worms from breeding, and consequently you will not be bothered that year. If you keep it up every spring you will finally forget there ever was any such pest, and you will also get rid of the little ground-flea. I know these things from experience.

Can I not change metal-cornered frames to reversible by getting some of your wire attachments?

Can you make me a bee-hat with rim of galvanized wire? My bee-hat is so pleasant to the head I will wear it all the time; and when it gets wet from a shower it rusts through the cloth. I also want a longer veil, with one-half silk brussels net and the other grenadine at least six inches longer. I am a very tall man, with a long neck. I am six feet five inches. My neighbors say I am just such a looking man as E. France. J. T. McCracken.

Rowell, Ala.

Friend M., it may not be profitable to use salt in the quantity you mention, on our corn ground, unless, indeed, the salt would have some other beneficial effect in keeping away the cut-worms; but in market-gardening it would no doubt be worth all its costs, and more too, where cut-worms are as troublesome as they are at times. Some recent reports in the agricultural papers seem to indicate that strong doses of common salt on some soils have a very marked

and decided benefit; but on other soils the salt seems to do no good whatever. We should be glad to have Prof. Cook tell us if he has heard of salt as a remedy.—To be sure, you can cut off the arms of your metal corners, and put on reversing wires. In fact, they were devised specially for this very purpose; or they are to be used on any hanging frame after cutting off the projection on which the frame hangs.—We can easily make a bee-hat with a rim of galvanized wire, but we hardly think the advantage of sufficient importance to warrant the extra expense. As the cloth will become sweat-soiled in a season's use there would in reality be no advantage.

A GOOD QUESTION; PUMPING WATER IN THE CELLAR TO KEEP THE BEES QUIET.

Does pumping fresh water occasionally in cellars keep bees quiet? Last winter I had some small carp in a barrel. I pumped a barrel of fresh water every week in the cellar, and the bees kept quiet. When I took the fish out I stopped pumping, and then the bees got restless. I then commenced pumping water in again, and they kept more quiet. Now, who can answer? Did the water purify the air, or did I only think so? My cellar is cemented on the bottom, and has tile to let the water out, and gas-pipe laid from the pump, so there is no carrying of water.

My bees did tolerably well through the fall. It was quite late when I got time to extract my honey, so that I had to put a stove in my honey-house to warm the combs before I commenced working with the bees. I shut the entrance *just so one or two* bees could pass out at a time at all the hives. Then I took all the honey away from the bees and set it in hives in the honey-house. I extracted it, and hung the combs in empty hives in the apiary, for the bees to clean up. There was only one hive that they commenced to rob at which I had neglected to close the entrance. The combs were all cleaned up nicely.

I got 1300 lbs. of honey from my bees this fall, all extracted. White clover yielded just enough to keep the bees going till the fall flow.

GEORGE J. KLEIN.

Conrad Grove, Ia., Dec. 14, 1888.

Friend K., if your cellar is remarkably dry, it may be that the moisture supplied to the atmosphere by pumping the water had the effect of keeping the bees quiet. A spring or running stream through the cellar has been many times considered a decided advantage.

BASSWOOD PLANK; DISCOLORATION OF, AND WHY.

Have you had any experience in drying basswood plank for sections, in a dry-kiln? If so, does the drying process color the basswood? How many thousand sections does one of your section-sawyers saw per day, and what wages do you pay them? I am paying 40 cents per thousand for sawing them, and think it is too much. J. M. KENZIE.

Rochester, Mich., Jan. 7, 1889.

Friend K., we have dried a great many thousand feet of basswood lumber in a dry-kiln heated by steam, and we have never experienced any trouble from discoloration as a result of such drying. Stained basswood lumber is generally caused by the timber being cut in the summer time; or even

if cut in the winter it will color if piled carelessly. Basswood timber should be cut in the winter, and, when piled up properly, will cut nice white basswood plank. Our sawyers cut about 500 sections per hour—that is, they rip the bolts into strips. We pay from \$1.25 to \$1.50 per day; and if you can get them cut for 40 cts. per thousand, and not have a good many spoiled by hurrying, you are getting the work done pretty reasonable.

A RETURNING QUEEN.

In hiving a swarm the past summer, the bees kept clustering on the hive, but would not stay in. After considerable search I found the queen under the projecting cover. I caught her as carefully as I could with my hand, removed the cover, put her on the frames, but in shutting the cover carefully she escaped. It looked as if a small hummingbird darted away, apparently back to the old hive. I hastened there, but could not see her enter, so I concluded to put the bees back. In doing so I detected the queen again on the top of the cover, surrounded by bees. I succeeded in putting her in the new hive, when the bees soon followed. It was something new to me, a queen leaving her bees and returning to the new hive, rods away from the old one.

F. J. M. OTTO.

Sandusky, O.

Friend O., it is true that a queen on the wing looks something like a small hummingbird, and especially to an enthusiastic novice whose eyes are apt to magnify every thing pertaining to a queen. But for all that, I am inclined to think that your queen did not go back to the parent hive at all. Never try putting a queen into the top of a hive, especially where you have to put the cover on the hive afterward. Put her down at the entrance, as she will be much more likely to go in. If you can start some of the bees to traveling in before you set her down, she will be almost sure to run in with them.

THE LAST ECLIPSE, AND WHAT EFFECT IT HAD ON BEES IN SAN JACINTO, CAL.

I suppose you all know that there was an eclipse of the sun the first of January; but I don't think you know what effect it had on *bees* in its path—at least not all of you. The day was a pleasant one here, it being clear and warm until the eclipse came over the sun, when the mercury went down from about 75 to 45 degrees; and the "manzanita" being in full bloom, my bees were bringing in honey and pollen by the wholesale; but the sudden change chilled thousands of the poor little laborers so that they were not able to get to their homes. Many dropped within a few inches of their hives and perished there, loaded with honey and pollen. I believe it would be a good plan for every bee-man to be ready for the next eclipse of the sun, and close all his hives early in the morning of such day, and, by so doing, save thousands of very valuable creatures from so sudden and unexpected an end of existence when life to them is so sweet.

San Jacinto, Cal., Jan. 7, 1889.

D. W. ROWSE.

Friend R., I think you exaggerate the damage done by the eclipse. From what I remember of the way the sun goes down in California, I can readily imagine how dark and chilly it became in a short time; but, if

I am not very much mistaken, the bees scattered around on the ground and trees would, a great part of them, revive the next day under the influence of the sunshine, and go back home to their hives. I have often seen pollen-laden bees go out so late as to be obliged to roost on fences or side-walks over night; but these same bees, when the sun strikes them in the morning, rub their eyes and stretch their legs and wings, and finally go home, none the worse for camping out, unless it be the tooth-ache, rheumatism, or something of that sort, later on.

TREATING FOUL BROOD; REASONS FOR FAILURE.

Some time last winter I wrote to you about the trouble I had with foul brood in my bees. I followed your kind advice as regards treatment, and not only put them in clean new hives, foundation, etc., but moved them three miles in the country to my present place. I found the treatment cured the Italian stocks, but not the hybrids. Some of these were brushed off their combs of brood on to foundation, and given clean hives three times. I had no cellar to starve them in, and found it a trouble to get them to take medicated syrup, the season being well advanced, and some honey being gathered. So I expect to see the enemy again next season. I requeneed the hybrid stocks the last time they were brushed off, and, having no brood to feed, they filled up for winter on buckwheat honey. I think it's the nervous nature of the hybrids when they are disturbed, causing them to gorge themselves to the utmost with the infected honey, that makes it difficult to cure them; however, I hope to see the last of the trouble next season, and hope to have a better crop.

E. ROBINSON.

Glendale, Westminster, Ont., Jan. 3, 1889.

Friend R., we can assign no cause for failure in our method of curing foul brood in your case, unless it be that you did not *compel* the bees to convert the honey they might have in their sacs into comb. Every drop of affected honey must be gotten out of their honey-sacs, either by starvation or by building comb, otherwise the treatment will be a failure. If there had been considerable natural stores, it would have been well to close the hive at night, after putting the bees in a clean hive, and kept closed for a couple of days. We had no trouble at all in curing when we starved the bees or caused them to build comb. If you had starved your hybrids, or made them build considerable comb, all would have been well.

TO TAKE PROPOLIS OFF A PAINTED FLOOR.

Take an old whisk or brush broom and a cup of boiling water, and hold the cup of water in one hand and pour on spots, and with the whisk broom scrub the spots. If only a little is on the floor, I use an old teaspoon to scrape it up, as a knife (unless very dull) is apt to scrape off the paint, and sometimes roughen up the wood, if pine. In our honey-house, which has a hard-wood floor, unpainted, I use the scraper that I scrape the bottoms of hives, first wetting the floor with cold water, if it is not convenient to have boiling water.

Roseville, Ill., Jan. 1, 1889. MRS. L. C. AXTELL.

REPORTS ENCOURAGING.

FROM 90 TO 140, AND 6000 LBS. OF HONEY.

MY report for last year is as follows: From 90 to 140, and about 6000 lbs. of honey—4000 lbs. comb, and 2000 lbs. of extracted. I moved my bees in April over 200 miles, and got them through all safe. It was a very hard spring on bees. I had about 80 fair colonies, and 10 of them were nuclei. These were used for rearing queens. White clover was fair, and the bees built up in good condition for the basswood-honey flow, which was good for about two weeks. My bees are all in the cellar, except two which are packed on their summer stands. I have 138 full colonies in the cellar, and 7 nuclei. The cellar is 11x13, and about 7 feet high. The bees all have a good woolen blanket on top of the frames, and a 6-inch entrance to the hive. The temperature has been from 45 to 50° all winter. The bees seem to be doing well. We are having a big snowstorm to-day, and I expect it will be cold now. White clover looks very well now. I am looking for a good honey crop this year.

N. STAININGER.

Tipton, Iowa, Jan. 9, 1889.

OVER 700 LBS. FROM ONE COLONY AND ITS INCREASE.

I extracted over 700 lbs. of well-ripened honey from one colony and its increase, and they had abundant to winter on. Who can come up to it?

Orion, Wis., Jan. 10, 1889.

F. L. SNYDER.

1100 POUNDS FROM 13 COLONIES.

I commenced the season with 15 hives of bees. I used two swarms for raising queens. With the other 13 I got 1100 well-filled one-pound sections, and increased to 52. They are in the cellar, and wintering well so far. My honey is all sold by peddling. I liked selling it, first rate.

JOHN RAGAN.

Waukon, Iowa, Jan. 10, 1889.

FROM 19 TO 40, AND 2000 LBS. OF HONEY.

I commenced the season with 19 colonies of bees (very weak), and increased to 40; took off about 2000 lbs. of honey. About all was sold at 10 cts. per lb. for extracted, and 15 for comb. I have no trouble to sell my honey. Where I sell one year I can always sell the next. My bees are all in good shape to winter. So far we have had a very open winter.

Bucklin, Mo., Jan. 9, 1889.

J. W. SWITZER.

FROM 80 TO 100, AND 4200 LBS. OF HONEY.

I commenced the season with 80 colonies, mostly strong. I had 20 natural swarms, making a total of 100. They were all very strong when I put them into winter quarters, with plenty of honey for winter stores. Surplus honey taken from them this season in 1-lb. sections, 600 pounds; extracted, 3600 pounds. How will that do for such a poor season as we have passed through?

HONEY FROM BUCKWHEAT.

I had a fair yield from buckwheat. I got 1300 pounds of surplus. I had one colony standing on scales, and it gained 25 lbs. in four days, and 11 lbs. in one day.

I had $\frac{3}{4}$ of an acre of Japanese buckwheat. It yielded well, both grain and honey. There was other buckwheat in the neighborhood. So you see if the weather is favorable it will yield honey with

us. Even if it is not very good, it is honey this year. It is worth ten dollars a hundred more than we can get for clover or basswood other years. From one peck of Japanese buckwheat I thrashed 18 bushels of good clean seed. D. ANGUISH.

Brantford, Ont., Jan. 11, 1889.

FROM 20 FAIR TO 42 STRONG, AND 2500 LBS. OF HONEY.

I produced 2500 pounds of honey this season from 20 hives in the spring, mostly weak. I closed the season with 42 strong colonies. I had single stands that made me 225 pounds of comb honey in pound sections. Considering the season, I thought my yield was worthy of a report. H. LATHROP.

Browntown, Wis., Jan. 9, 1889.

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

All queries sent in for this department should be briefly stated, and free from any possible ambiguity. The question or questions should be written upon a separate slip of paper, and marked, "For Our Question-Box."

QUESTION 103.—*What do you consider to be the best covering for frames in winter, regardless of a few cents' difference in expense—woolen ingrain carpet, muslin, linen, duck, enamel cloth, or burlap?*

Woolen or straw, most assuredly.

CHAS. F. MUTH.

The cover of the hive—nothing more.

H. R. BOARDMAN.

I do not think it makes much difference, if the bees are properly prepared for winter.

A. J. COOK.

We use a straw mat; but of all you mention, we would use woolen carpet.

DADANT & SON.

The enamel cloth is what I use, because I find the bees eat it less than any other material.

P. L. VIALLO.

I use burlap, the same as is on in summer. I leave it as the bees fix it in summer. I would use enamel cloth if I had it.

DR. A. B. MASON.

Light woolen first; burlap second; muslin third. I have no use for linen, duck, or enamel cloth, for a winter covering.

MRS. L. HARRISON.

First I use a sheet of duck or common factory cloth over the frames, then over this I use a cushion from 3 to 4 inches thick, made of factory cloth filled with dry basswood sawdust.

G. M. DOOLITTLE.

I use neither, but leave on the honey-board. This gives the bees about $\frac{3}{8}$ inch space over the frames; and the honey-board, being slid forward about $\frac{1}{4}$ inch, gives all the upward ventilation I want them to have.

GEO. GRIMM.

I suppose this question refers to covering for open-top frames; and if so, I can not answer it. I consider a good chaff cushion the best covering I know of for any kind of frames, not only during winter but summer as well.

O. O. POPPLETON.

For indoor wintering I prefer enamel cloth with any kind of a mat over it. For outdoors I would use enamel cloth with a heavy cloth or mat over; and over and around all, four to six inches of loose packing of leaves, chaff, cut hay, or straw.

L. C. ROOT.

I use enamel all the year round, whenever supers are not on. I am not positive it is the best thing; but it seems to me that a contracted chamber, tight on the top and all sides, gives them power to ventilate by the entrance, when they wish to do so, better than when their covering is porous.

E. E. HASTY.

That depends upon the hive somewhat. It doesn't make so much difference if you have a board over it. If you depend upon these alone for upward ventilation, then neither is warm enough. I think I would as soon have a board well glued down as any thing. Our hives are so constructed that we have to use something else, so use a burlap quilt filled with cotton.

P. H. ELWOOD.

Enamel cloth with woolen carpet over it. But I don't use that, and I like mine well—a single thickness of muslin (sheeting) well glued by the bees, and over it a quilt made of sheeting with several thicknesses of newspaper in it. Perhaps it would be just as well to have a single thickness of sheeting and another hive fitting closely over it.

C. C. MILLER.

It makes no difference. A board cover I have found just as good as any thing. You were straining at a gnat and swallowing a camel. Bee diarrhea is what sweeps away our stock, and you can not prevent it in the least by the use of woolen ingrain carpets, muslin, linen, duck, enamel cloth, or burlap. If there is no nitrogen in the food they are to consume during confinement, then you will be all right with any of these covers or none of them.

JAMES HEDDON.

I prefer enameled cloth. I want the top of my hives as closely sealed and as nearly airtight as possible. Many of my hives have board covers, and I like to have the bees seal them down tight as long as possible before winter.

I am more firmly persuaded than ever, that, with proper protection, no upward ventilation whatever should be permitted. I have wintered bees in tin cans (as near as I could conveniently get to the glass bottles we talked of a couple of years ago), with good results and no loss.

JAMES A. GREEN.

I am glad to see, friends, a disposition to decide that it does not matter so very much what the covering is, providing all the circumstances are as they should be. Now, an enamel cloth waxed down tight will do very well, providing you have a chaff cushion, or its equivalent, on the top of the enamel cloth. If you have simply an upper story over it, so the frost can get in and reduce the temperature of the upper side of the enamel cloth, it will act exactly like a pane of glass on your windows in the winter time; namely, the under side will be covered with dampness, or may be a thick coating of frost; whereas, were the frost kept away by means of a good chaff cushion on the upper side there would not even be any dampness on the side toward the bees. Put a chaff cushion or pillow tight against one of the panes on your window, on a cold frosty night, and you can see it for yourself. There will be no frost on the outer side, while all the rest of the panes will have a thick coating of ice. The other condition is, as has been mentioned, that there be venti-

lation enough below, either through a hole made in the bottom of the hive, or by having a good-sized entrance. If the entrance gets clogged, or is small, a sheet of burlap over the bees might save them, when they would die with the enamel cloth.

QUESTION 104.—How and in what way can a bee-keeper best employ his leisure hours in the winter months, to advantage?

Prepare for next season's work. GEO. GRIMM.

Making hives, selling honey, and reading.

DADANT & SON.

Making preparations for the next season, and writing for the bee-journals. H. R. BOARDMAN.

Feeding his chickens, tending the baby, and making himself generally useful. MRS. L. HARRISON.

There are many ways to do good during the winter months, too numerous to mention.

CHAS. F. MUTH.

This can hardly be answered. He can arrange for the coming season; can market his honey at retail, often at a good paying remuneration. It depends much on his tastes and adaptability. A. J. COOK.

Reading and studying the theory of his business, and doing such apiary work as can be done at that time of year. He can read other good literature, get acquainted with his family, and have a good time generally, besides.

JAMES HEDDON.

In doing all such work as can be done at this season, to be in readiness for the busy season with the bees. Don't wait till you need hives, boxes, frames, etc., before preparing them. Some time should also be given to reading and study.

L. C. ROOT.

Work at the trade he had before he was a bee-keeper; teach school; chop cord wood—no, I guess you mean as a bee-keeper. Read, read, think, plan, subscribe for more bee-journals, get more bee-books, attend conventions, visit other bee-keepers (if he thinks it won't bore them), get ready his hives, sections, and other things he'll need for the coming season.

C. C. MILLER.

If he has not made bee-keeping pay during the last five years, he had better spend his time in looking up some other business to take its place or add to it. I say this because I think we can not for the next five years look for any thing better. Supplies can be got ready for another season. If these are all ready, and he can not think of any thing that needs doing, he can—hibernate! P. H. ELWOOD.

In getting every thing he may need ready for the busy season—that is, taking for granted that they are in other business, which the majority are. For my part I give part of these leisure hours to field sport, as I find that I enjoy better appetite and health when I take a hunt every week during the winter. A few hours in the field, with good birds and a good gun is not only a pleasure but a fine tonic.

P. L. VIALLO.

Circumstances surrounding each individual bee-keeper vary so much that each one will have to answer this question for himself. Of course, he will have no leisure time until all work in preparation for next season's operations in the apiary, that can be done in the winter, is done. Some occupy their

time in study, some in teaching school, some in chopping wood, and other work for wages. This is an important question to all persons whose trades can not be followed during the winter, and each one will have to do that work which is the nearest him that he is fitted to do. O. O. POPPLETON.

I can recommend my own way, without much fear that any one will name a better way. Spend the spare hours, both winter and summer, in spreading the knowledge of the truth as it is in Jesus Christ. Still, many brethren would vote my way one of the worst that could be invented, and pronounce all who hold the faith as I hold it, to be mere vermin, beneath notice. E. E. HASTY.

If employment outside of bee-keeping is meant, each must decide for himself according to circumstances, and his own opportunities and capabilities. There are two ways in which a bee-keeper may very profitably employ his winter months. The first is in preparing every thing needed in the apiary, ready for immediate use the next summer. The second is in putting his product in the best possible condition for market, and then disposing of it to the best possible advantage. A little effort in this direction will bring very large returns. Many bee-keepers do not get nearly as much for their honey as they might. JAMES A. GREEN.

First, in serving God and doing our part in preparing for that future state of existence upon which we must all soon enter. Need I say that a large part of this work is in making yourself lovable by being always cheerful, and doing good to those about you for Christ's sake, thus allowing the light that is in you to shine out before the world for the Master's honor and glory? Get away from self, and enter heartily into that which shall make the world better, and advance the cause of our God and his kingdom. Second, post yourself intellectually regarding our beloved pursuit, bee-keeping, by reading what you can on the subject. Third, get every thing ready for the busy season of the next year, so as to be prepared for the large yield of honey which is coming. G. M. DOOLITTLE.

A bee-keeper should have no leisure hours; that is, hours in which he has nothing to do. Hours in which we do nothing but rest, both mentally and physically, are sometimes the most profitably spent. If the welfare of the spiritual part has not been provided for, I know of nothing in which the bee-keeper could better employ his leisure or any other hours than in making such provision for it as is desirable for present and eternal enjoyment.

'Tis religion that can give
Sweetest pleasure while we live;
'Tis religion must supply
Solid comfort when we die.

Another profitable way is to become better acquainted with one's neighbors. Oh, dear! I give it up; I can't answer that question. It is too "big" for the Question-Box. I never saw the time in which I didn't have or couldn't find something to do. I wish the hours were twice as long, then perhaps I could come nearer doing all that I should like to do. Now, don't let any one pitch into me for a discussion on the subject of religion, unless he incloses stamps for reply, and to pay for time, paper, and envelopes. There, Ernest, that looks pretty long for the Question-Box. Cut it to suit you, or leave it out entirely. DR. A. B. MASON.

I think, friends, that very much depends upon one's circumstances. A bee-keeper who is in debt, and who is constantly pressed by his debtors, ought to work hard at something all winter long, and I think he will find as much enjoyment in this way as in almost any of the things that have been mentioned. If he is comfortably off, he certainly ought to devote a good share of his time toward helping and encouraging those who always need help and encouragement round about him. I am very much pleased to see how many there are among our number who urge the importance of following Christ's last commission which he laid upon us—"Go ye into all the world and preach the gospel to every creature." This does not necessarily mean that we should go to foreign lands as missionaries, nor that we should feel that we are called upon to climb up into a pulpit. "Whether ye eat, or whether ye drink, do it all to the glory of God." When it comes to having real fun, I think every bee-keeper should have a greenhouse, so he can be happy in watching for sunshine, and in seeing things grow.

QUESTION 105.—*What do you do when you find a colony affected with dysentery in the cellar, and it is too early or too cold to give them a cleansing flight by removing them temporarily from the cellar?*

I do nothing.

GEO. GRIMM.

We let them go.

P. H. ELWOOD.

I generally let them alone, except to make the cellar warmer.

C. C. MILLER.

Nothing can be done, and we would not even look, for it does them harm to be disturbed.

DADANT & SON.

I place a wet cloth over the brood-frames, or throw a handful of salt into the entrance, or both.

CHAS. F. MUTH.

I do not winter in cellar much. I should do whatever I could to make them more quiet; and, beyond that, let them alone as much as possible.

E. E. HASTY.

I just let them alone and lose them. In nine cases out of ten, the more you tinker and fuss with them, the quicker they will die and the more you will lose.

JAMES HEDDON.

I mean to prevent this. I have cured them by giving them a flight in a warm room. This is best done by putting them in a large box and covering with netting.

A. J. COOK.

I have not had a colony affected with diarrhea in the cellar in years; and if I were to have, I would simply let them alone; for, as far as my experience goes, fussing with this never does any good.

G. M. DOOLITTLE.

I would let such colonies alone. The disturbance will injure others more than it will help those affected. If such a stock were at the bottom of the room it might be a benefit to raise it to the top, where it would be warmer.

L. C. ROOT.

I let them alone. If the bees are all right, and have suitable stores when put into the cellar, and the cellar is properly ventilated, and kept at the right temperature, say 38 or 40°, there will be no dysentery.

MRS. L. HARRISON.

I put them in a room of the bee-house in which is a stove, and warm them up to nearly 100° for several hours at a time, keeping the room perfectly dark, giving the hive free ventilation at top and bottom, and repeat the dose at intervals of several days if necessary.

H. R. BOARDMAN.

I let it alone, for none of my colonies are so badly affected as to need attention. I aim to have each colony provided with proper food in the fall, and then kept at the right temperature in the winter, and I have no trouble in wintering. Pollen, or bee-bread, is not a proper winter food for bees; and because "Rambler" saw the "pollen theory" "go up in a balloon" is no evidence that the theory is not correct.

DR. A. B. MASON.

This is a subject that was discussed largely in the bee-papers just before GLEANINGS was born; and while I never experimented in giving cellar-wintered bees a cleansing flight, I have done so largely with bees that were being wintered out of doors. I did this by letting them fly on top of the hives in a shallow box covered with glass, the rays of the sun through the glass giving heat enough for the purpose when the outside air would be freezing. These experiments led to my learning the value of chaff as a winter protector for bees, and the use of the solar wax-extractor; but I am not satisfied that it was of material benefit to diseased bees. This experiment can be easily tried with cellar-wintered bees by removing them temporarily to a light warm room and putting on them a box some 5 or 6 inches deep, covered with glass, after opening the top of the hive so the bees can come up freely on top of the frames. While I have little faith in the practical value of such an experiment, it will cost but very little to try it, and may be of greater value than I think for.

O. O. POPPLETON.

Our older readers will remember that, about the time GLEANINGS was "born," as friend Poppleton expresses it. I had a greenhouse, or, rather, a large cold-frame, built on purpose to cure bees that had the dysentery. Well, it worked tiptop, providing we had warm sunny days, so the bees could be put outdoors not very long after they were cured (?) by the treatment in the greenhouse. If we didn't have days when they could be set out, and given a good fly under the blue vault of heaven, they had a kind of fashion of relapsing, and ultimately "going dead" in spite of the cure. They were not exactly like the Irishman's bird, that he shot as plainly as could be, but wouldn't die because it was so contrary; for after they had been doctored and cured, as plainly as could be, they died, just to be contrary. May be, if I had pushed my investigations further I might have triumphed over the difficulties; but, if I remember correctly, just about the time of these experiments, our good friend P. H. Elwood wrote to me, that even if they could be cured by the greenhouse treatment, it cost more than to buy some good healthy bees of somebody who had them, in the spring. At the low prices at which bees have been offered for some time back, it does not pay to fuss very much with weak and sickly colonies, providing one has some other occupation that pays him fair wages.

NOTES AND QUERIES.

We solicit for this department short items and questions of a practical nature; but all QUESTIONS, if accompanied by other matter, must be put upon a SEPARATE slip of paper with name and address.

A GOOD REPORT FROM ONE OF THE FRIENDS IN CALIFORNIA.

IT would do you good to see my bees tumbling in with pollen to-day. The tomato-vines that you saw on my fence are maturing fruit every day, and the hills of corn you saw are now in silk.

We have had more rain, and the prospect for a honey crop is good. I have not been able to decide whether I will go to the mountains this spring or not.

W. J. MORRISON.

Long Beach, Cal., Jan. 7, 1889.

I raised 32 bushels of Japanese buckwheat from $\frac{1}{2}$ bushel I got of you.

J. V. HURLESS.

Archer, O., Jan. 14, 1889.

PAINT FOR HIVES.

I have used lead oil, but I find a paint made by Lonoman & Martinez, of New York, wears best. Some of my hives have been painted five years with that paint, and are still in good condition.

Sara Sota, Fla., Jan. 8, 1889.

S. C. CORWIN.

DRONES IN WINTER.

Can you tell me how it is that I have drones in one of my hives at this time of year, Jan. 8? I never saw it before.

SETH TOMPKINS.

Tarrytown, N. Y.

[Friend T., the presence of the drones you mention is probably due to the mild weather. If such weather should continue they may be found in the hive throughout the winter. You will probably find considerable worker brood in the hives.]

AN EIGHT OR TEN FRAME HIVE FOR COMB HONEY.

Were you working for comb honey, and did not care to practice contracting the brood-chamber, would you prefer an eight or ten frame hive, of S. size?

A. B. BAIRD.

Belle Vernon, Pa., Jan. 7, 1889.

[Friend B., as your question states it I should prefer an 8-frame hive. Usually they would not require contraction with dummies.]

HIVES WITH DEAD-AIR CHAMBERS.

In having a dead-air chamber in a hive, would you have it between the packing and the outside wall, or would you have it between the packing and the bees?

H. F. GRESSMAN.

[You don't need a dead-air chamber if you have packing around the bees. It is used only when no packing of any kind is made use of. A chaff hive without chaff between the walls would be a dead-air-chamber hive; but if you insist that you want, in your locality, the dead air and packing both, it seems to us it would be immaterial whether the air-space were between the outside wall and the chaff, or the chaff and the inside wall.]

REPORT FROM OUR FRIEND DR. LAY.

We have had a very prosperous year in every thing except honey, and that a fair crop. Bees are in good condition, and all honey-plants are up and well advanced. We have had a wet season. We are yet enjoying garden vegetables. You were within 18 miles of our home when you were at Schulenburg, on your trip to California. I am sorry you could not stop with us. We are happy to note that GLEANINGS is improving all the while.

It is read by us with much pleasure.

J. E. LAY.

Hallettsville, Tex., Dec. 28, 1888.

TEXAS AND THE HORSEMINT.

Our main honey-plant here is horsemint, and I am fearful it will be scarce this year. It has been a warm wet winter so far, and there is a great deal of horsemint up and green, which will be killed if there comes a freeze, and I am afraid it will leave but little seed for spring. There is now blowing the coldest "norther" that has been felt this winter.

W. A. CARTMELL.

Crowley, Tex., Jan. 8, 1889.

PROSPECT FOR THE HONEY CROP IN TEXAS FOR 1889 NEVER BETTER.

The prospect for a big honey crop was never better in this part than at present. We have had a warm wet winter, and the horsemint is making its appearance in all of the waste places, and in many places even the wheat and oats on the cultivated lands. Yes, and the buds on the elm are swelled and bursted, and will be in bloom in a few days, and then our little Italian pets will be in their glory.

Cross Timbers, Texas, Jan. 14, 1889. L. B. SMITH.

SWARMING OUT IN JANUARY.

On Christmas day one colony of my bees rushed out and clustered on a tree. They stayed three or four minutes, separated, and went into three different hives. They were all right, but had to fight their way into the third hive. They swarmed out, probably because they had a sickly-looking queen, damp hive, and very little stores left behind. About 12 bees remained with the queen.

Wetheredville, Md., Jan. 9, 1889. J. A. HEIDLER.

[Friend H., I believe you are correct in your reasoning. Where bees get damp, they often swarm out in the way you mention. The dampness is usually caused because the cluster of bees is too small to produce sufficient heat to dry out the combs and bees.]

HONEY FROM HARD MAPLES.

Having noticed in GLEANINGS that there is a difference of opinion as to whether or not bees store honey from hard maple, I wish to state that last spring, before there was any other source of honey, I could have extracted more than 1000 lbs. of maple, or sugar-tree honey, but did not take much on account of its oily flavor. I have a 3-lb. can of pure honey from that source yet, and can send it to you if you would like to have it.

Clarksburg, Ind., Jan. 8, 1889. H. F. SHANNON.

[Friend S., I do not quite understand what you mean by the term "oily flavor." If you mean something like what we call "buddy," applied to the last sugar or molasses of the season, then I think I understand you. You may send us a sample of the honey by mail, in the little wooden block we mail you for the purpose.]

IN STRAIGHT ROWS.

Mr. Axtell says if trees are planted in perfect squares, or in straight rows two ways—that is, perfect rows east and west, and perfect rows north and south, then the diagonal rows will be perfectly straight and there will also be an infinity of them, provided the orchard be large enough. For proof of the above, you would only need to see one of our large cornfields when six inches high, that was planted perfectly with a check-rower.

Roseville, Ill.

Mrs. L. C. AXTELL.

[I know a check-rower will do it, my friend, if the operator is very careful to start on a line when he commences at each end; but the orange-trees in California were set so very exact that it made me think they had some new process for doing it rapidly and quickly. You will notice that the subject has been taken up by two other writers in this issue.]

TOBACCO COLUMN.

CONDITIONS UNDER WHICH WE GIVE SMOKERS TO PERSONS WHO STOP USING TOBACCO.

First, the candidate must be one of those who have given up tobacco in consequence of what he has seen and read in this department. Second, he promises to pay for the smoker should he ever resume the use of tobacco in any form, after receiving the smoker. Third, he must be a subscriber to GLEANINGS. Any subscriber may, however, have smokers sent to neighbors or personal acquaintances whom he has labored with on the matter of tobacco-using, providing he give us his pledge that, if the one who receives the smoker ever uses tobacco again, he (the subscriber) will pay for the smoker. The one who receives the smoker in this case need not be a subscriber to GLEANINGS, though we greatly prefer that he be one, because we think he would be strengthened by reading the testimonials from time to time in regard to this matter. The full name and address of every one who makes the promise must be furnished for publication.

WE extract the following from the *Independent* of Jan. 10, hoping it may carry conviction to the heart of some tobacco-using brother:

"A great majority of men go far beyond what may be called the temperate use of tobacco, and evidences of injury are easily found. It is only necessary to have some record of what the general health was previous to the taking-up of the habit, and to have observation cover a long enough time. The history of tobacco in the island of New Zealand furnishes a quite suggestive illustration for our purpose, and one on a large scale. When Europeans first visited New Zealand they found in the native Maoris the most finely developed and powerful men of any of the tribes inhabiting the islands of the Pacific. Since the introduction of tobacco, for which the Maoris developed a passionate liking, they have from this cause alone, it is said, become decimated in numbers, and at the same time reduced in stature and in physical well-being so as to be an altogether inferior type of men."

Mrs. Leeka has quit smoking, and she helps me with the bees. Please send her a smoker. If she takes to the weed again, I will pay for it.

THOS. W. LEEKA.

Losantville, Ind., June 15, 1888.

My husband has quit the use of tobacco in every form, after using it since he was a boy. He says if you send me a smoker, and he ever uses tobacco again he will pay you your price for the smoker.

Jantha, Mo., Aug. 3, 1888. E. C. HARPER.

I thank you most heartily for the *smoker* for my son, and freely promise to pay for the same, if there should be any falling back into evil habits. But I think that will never be, for my son has experienced religion.

MRS. J. E. BUTTOLPH.

Frasa, Tex., Nov. 2, 1888.

GOING BAIL FOR A NEIGHBOR.

A neighbor of mine has quit the use of tobacco through reading GLEANINGS, and my influence, and wished me to write for a smoker. He will pay for it if he ever uses tobacco again, and I am ready to pay for it if he don't. He has just commenced bee-keeping and has the A B C book.

Berlin, Wis. E. C. EAGLESFIELD.

TEN CENTS A DAY FOR TOBACCO, FOR TEN YEARS.

I quit using tobacco in every form, Nov. 5, 1880, after chewing an average of 10 cents' worth (?) a day for ten years. I shall stay quit, and I don't ask anybody to give me any thing for quitting or staying quit. The pleasure of doing without tobacco is far greater than the doing with it was to me.

J. A. GEETING.

Washington, Ind., 1888.

A MINISTER AGREES TO QUIT THE USE OF TOBACCO.

Rev. Giles M. Johnston, a young minister of the gospel, agrees to quit the use of tobacco; and if you will send him a smoker, I agree to pay for the same should he ever commence the use of it again.

G. C. HUGHES.

Pipestem, W. Va.

A BROKEN PLEDGE, BUT PAYS FOR THE SMOKER.

Please find 70 cts. to pay for a smoker that I sent for in 1887, for J. D. Stringer, who had quit using tobacco. He finally let the disease take hold of him again. He says the thirst is too great for him to resist. Please accept our thanks for your liberal effort to put down such a filthy, sinful habit.

J. H. MORRAN.

Dripping Springs, Tex., Sept. 23, 1888.

A GOOD REASON FOR STOPPING THE USE OF TOBACCO.

I have been in the filthy habit of using tobacco for two years; but by reading your Tobacco Column, and by taking advices from friends, I have concluded never to use such vile stuff again. Recently a young lady friend told me if I would not quit using tobacco she would not speak to me any more. How is that for tobacco? I am now 20 years old, and have been using it since I was 18. I never used it in any other way than smoking. I think your Tobacco Column is good. I should think it would turn a good many hearts from using tobacco. If you think I deserve a smoker, please send it; and if I ever in my life use tobacco again I will pay for two smokers.

A. A. RIEFF.

Mankato, Minn., Nov. 7, 1888.

WHY I STOPPED THE USE OF TOBACCO.

I did not quit tobacco by what I read in GLEANINGS, but I was a subscriber for GLEANINGS in 1885, and it might have had its influence. I quit tobacco in order to get a clean heart. I could not puff tobacco smoke in God's face, and ask him to bless me. I could not use tobacco to the glory of God, nor come to him with a clean mouth, and I could not enter into the holy of holies with my clothes saturated with the fumes of hell. I could not shoot God with the devil's best gun (tobacco), and claim to be on the Lord's side. I could not say, "God has taken me out of the depths of sin, but can't save me from tobacco." Jesus came to save his people from their sins. If I knew it would kill me to give up tobacco I would give it up, and go sweeping through the gates into the city of God. There will be no tobacco there.

EMSLEY L. FAULKNER.

Pentwater, Mich.

TWO YEARS AFTER HAVING QUIT THE USE OF TOBACCO.

Just two years ago to-day I quit the use of tobacco, after using it nearly thirty years. You may place the credit to friend Terry. His letter in GLEANINGS caused me to burn my stock of "Navy," and promise my dear wife never to use tobacco in any form again. I've do doubt you have a great many new subscribers that have never read his letter. Why not publish it again? Don't send me a smoker. You have never made enough of them to hire me to quit tobacco. Any married man who will "chaw" after reading friend Terry's article, and then promise to quit for a smoker, would, of course, swap his wife for one.

C. S. DOUBLEDAY,

Hamilton, Tex., Dec. 23, 1888.

OUR HOMES.

How amiable are thy tabernacles, O Lord of hosts! My soul longeth, yea, even fainteth for the courts of the Lord: my heart and my flesh crieth out for the living God.—Ps. 84:1, 2.

ANOTHER joyous and peaceful Sabbath (Dec. 9) is past. One of the happiest memories of my visit to California will be the pleasant meetings with Christian people. Saturday afternoon I found I had accepted all invitations except one, and my friends informed me the address was left by a young man who came on a bicycle, and who was quite deaf. He lived at Long Beach. I wanted to get off on my homeward trip, and I found two trains left at about the same time—one for Long Beach and the other for San Francisco. Which should it be? As I stood before the ticket-office I prayed for guidance. In a moment I decided. I found my friend building a new house, and not very well fixed to keep company over Sunday, and so I decided to go to the hotel; but he soon told me, with some hesitation, that, if I could put up with his quarters, it would save expense, and that I should be quite welcome. His "quarters" were a barn close by his new house, his wife being with friends until the new house should be finished. Now, it is a very common thing here to live in barns, and some of them very scanty ones at that; and I quite enjoyed the idea, especially as it seemed to promise an opportunity for me to discover what message it was the Master's wish I should deliver to this afflicted brother. After our supper at a restaurant, we sought our lodging-place. As it is remote from any house, I could talk as loud as I pleased, without being overheard. Deaf people often get very lonesome—did you know it? I was soon rejoiced to find my companion a sincere and devoted Christian, but he had met some perplexities, or, perhaps, conflicting advice, that he longed to submit to the author of "Our Homes," for he has taken and read GLEANINGS since it was a 25-cent quarterly. One of his troubles was that he had never been baptized, except in infancy, and somebody had told him such baptism was "no good." They had even loaned him a book to read, and he had compared the texts with the Bible, and they all "squared" exactly. I assured him there were multitudes of books that proved their teachings in this very way, and advised him to let the baptism rest right where it was, but to bestow his care and pains toward "doing justly, loving mercy, and walking humbly before God."

"But, Mr. Root, there isn't a word in the Bible about infant baptism."

"Neither is there a word about Sunday-schools, yet you and I are going to the very first one in the morning we can find."

He had actually been thinking of uniting with another church, just because his devoted and faithful parents had baptized him when he was too small to know any thing about it. His pastor did, it is true, consent to another baptism, but rather advised as I did, to let it remain as it was, and turn his

attention to things that were doing real harm.

"But, Mr. Root, one minister advises one way and another different. How can both be right?"

I told him it would be perfectly right for each one to follow the advice of *his* own pastor, in such matters.

"But, Mr. Root, I believe in taking the Bible exactly as it reads, without regard to any minister's advice;" but as he had his well-read Bible open on the top of his tool-chest, he pretty soon found a passage where it described an army "as the sands of the seashore," in numbers, and he was compelled to admit it was not to be taken literally, *as it read*.

"Well, Mr. Root, I think one ought to even black his shoes on Saturday night, to avoid working on Sunday."

"All right; that is a good and safe practical religion; bring your brush, and we will put it into practice at once."

"But, you don't need to black yours, according to your teaching, for you may not feel about it as I do."

"But I do think as you do to-night, any way; but if we get the blacking off in chasing after the horse in the morning, I should brush them up again, rather than to go to church with untidy shoes."

After we got to bed he questioned me as an eager child would; and when I got too sleepy to answer loud enough, he jokingly suggested I needn't be afraid of waking up the "people up stairs." At this I talked so loud a lot of geese the other side of the boards to the barn set up a cackle, and then we had a big laugh.

The joke about the upstairs was because the principal occupants were the stars of heaven.

"Mr. Root," said he, "were you ever tempted, when all alone by yourself?"

I told him that some of the hardest battles I had ever fought were in this very line, and his question took hold of me instantly.

"Well," he resumed, "did you ever try, at such times, singing a hymn?"

I told him I had never thought of it; but when he asked me if I would not sing one verse of some familiar hymn of my own, I felt it a privilege. Of course, I should have to sing quite loud to make him hear. It could not disturb any thing but the geese, and I had just had such a hearty laugh at the cackling that I was in very good trim to sing with energy. I sang, as well as I could,

"Guide me, O thou great Jehovah!"

At the close I asked him to sing something that had helped him when tempted; whereupon my poor deaf brother sang one of the most touching hymns I ever heard in my life. He commenced with a somewhat timid voice, but finally the beautiful sentiments seemed to give him inspiration; and I did not wonder at its close that such a hymn had power to banish evil spirits and evil suggestions. If he will write out the words I will at some future time give it to the readers of GLEANINGS.

When I was half asleep again, he pulled me by the shoulder, and suggested, "You forgot to wind your Waterbury."

"No, I didn't; I wind it *mornings*."

He replied with great gravity, "Do you feel sure it is right to do *so much work* (?) on Sunday?"

He gives a tenth of all his earnings to the Lord; but a while ago he was tempted to use some of "the Lord's money" to speculate in real estate, at the time of the "boom," but the real estate went down and the money was lost, and a good deal more with it; so he mortgaged some property to get the money to pay up (that is, the Lord's tenth) by giving the money thus obtained to benevolent and missionary work. Dare any of us say he went to *too great extremes* in this?

In the afternoon my friend suggested that we sit on the seats on the bluff, and read the Sunday-school papers we had received at school. As I looked a little demur, he suggested that it was no worse than to sit in the parlor of our boarding-place. I assented. On the way it occurred to me I should like to write a word or two to my wife, as we sat viewing the ocean; and as I looked up I saw paper and envelopes in a little booth on the sidewalk. Without a thought I extended a dime for the tablet in which I am now writing. Almost before the transaction was done, however, he stepped up and promptly and faithfully rebuked both of us. "Mr. Root, you are encouraging these people in *Sunday traffic*, and at the same time patronizing a tobacco-stand."

A pretty predicament for the editor of GLEANINGS, especially after all he has written about doing business on Sunday, and the use of tobacco—yes, and a spiritual adviser besides, whom *God* had sent.

I thanked him, and told him he was right. We sat on the bench on the cliff, but we did not look at the ocean much, and I didn't write my letter. We both began to feel we were not exactly where Christians ought to be, for many others were along the cliff and down on the roads. I had suggested visiting the jail, but they don't have any, for they never have had a saloon, and never expect to have one. May the good Lord direct two of his children this Sabbath afternoon. The prayer was answered very soon. A man came up rather out of breath, and inquired for A. I. Root. I at once jumped to the conclusion that he was the operator, and had a telegram for me, because something had happened at home. I started up.

"I am A. I. Root; what is wrong?"

"Nothing, only I have had a long hunt for you. I think I have been after you since about the time you saw those turkey buzzards 'nailed' up on the trees to dry."

At this there was a big laugh all around, and then he explained that their little girl came home from Sunday-school, declaring "*A. I. Root*" had been there. He assured her she must be mistaken; but she stoutly declared that the minister said, "Brother A. I. Root, of Medina, O.," would make the opening prayer, whereupon he set out to hunt him. He traced him to dinner, then to the Congregational Sunday-school, then off toward the ocean, and he thought probably he had gone off "hunting greenhouses" or something of the sort. How did he know

any thing about *me*? Why, he had taken GLEANINGS, even away back in Louisiana, and A. I. Root was a household word, even among the children. Would I not make his house my home while I stayed? How about visiting on Sunday? This new friend was a Baptist, the other brother a Methodist, and myself a Congregationalist. Surely we *three* ought to be able to decide how best to keep the Sabbath day holy under the circumstances. We accepted the Baptist brother's invitation, and, what do you think? It was close by the barn where we had stayed the night before. These two brothers were side by side in a far-off land, and yet both took and prized GLEANINGS, but might not have known it for weeks had I not made them acquainted. And it seems that almost every Sunday since I have been in California some *child* has spread the news of my whereabouts. I tell you, friends, it pays, in more ways than one, to be promptly on hand at both prayer-meeting and Sunday-school, no matter how old you are. Sabbath evening they had a wonderful temperance meeting, with all the pastors of Long Beach on the platform, and all the people (as a matter of course) filling the seats of a pretty good-sized tabernacle. I did not suppose so large an audience could be found, if every man, woman, and child attended; and I did not suppose the three pastors (although I had formed a very high opinion of them) could give us three such mighty temperance sermons.

I have praised California so much, perhaps I should touch lightly on its evils. Well, the Methodist pastor, in speaking on social purity, said that in Los Angeles alone there were four hundred—not men, but blots on creation—who made a business of enticing boys, and *girls too*, into houses of *ill-fame*. I hope this may be a mistake. I have been a good deal in the city of Los Angeles, and they seem to be a busy, God-fearing people.

Friend Morrison's good wife welcomed us to their home as warmly as did her kind husband; and even if we did visit some on Sunday, I believe the Savior looked down on us lovingly.

"O Mr. Root!" commenced our hostess, with her charming Southern accent; "there is one woman in this town I do wish you could know. She is rich, but she has so much of the grace of God that riches can not harm her. She has not only builded the Congregational church, but pays the minister almost herself." The speaker is a *Methodist*, and her husband a *Baptist*; but I believe this spirit is characteristic of Long Beach.

"Who is the beautiful lady that superintends the Congregational Sunday-school?" said I.

"Why, Mr. Root, you have seen her already."

I wondered, when I saw her giving directions, toward the close of the school, to see one with such a sweet, pure, childlike face, in a place of so much responsibility. She is the child of a Congregational minister; but her husband has been prospered, and has now immense wealth; but he evidently has as much faith in her as the rest of the peo-

ple there, for they too give very largely to all praiseworthy purposes.

Thus ended my fourth Sabbath in California, and also my 49th birthday, for it was the 9th of December.

MAPLE SUGAR AND SYRUP MAKING.

RECENT IMPROVEMENTS IN THE IMPLEMENTS.

Of course, bee-keepers can not all engage in the maple sugar and syrup industry, for they do not all have the maple-trees; and some that do, do not have the winter's frost; but almost all of them have a tooth for the products, therefore most of us are interested, either directly or indirectly, in the matter. The cut below shows a new cover, just brought out by the Record Manufacturing Co. Much sap is lost during windy days, by the wind; besides this, dirt, sticks, leaves, and insects, are blown into the sap, and certainly this does not improve the quality of the product. When the weather is warm and sunny, during a flow of sap, bees are also drowned by the thousands in open buckets. This cover obviates all these troubles.

NEW TIN BUCKET, WITH TIN COVER ATTACHED FOR MAPLE-SUGAR MAKING.

These covers also, to a large extent, prevent freezing; for if the chilling wind is kept from striking the surface of the sap, it will be less liable to freeze, so as to injure the buckets, or so as to interfere with the handling of the sap. Last, but not least, rain and snow are kept out. It seems a little singular, but it has been abundantly proven, that the addition of rain water always makes the product darker colored. It is the gilt-edged syrup that commands the big price, like gilt-edged butter and honey. The latest improvement in the way of spouts or spiles, is the one shown next.

This differs from the one we illustrated some years ago, only by having the small end closed entirely by a cap. Through this cap a small orifice is made. This prevents the air from getting up into the bore in the tree, and oxidizing, or souring, the sap

when the run is small, the little orifice being closed air-tight by a minute globule of sap. Price 90c per 100, \$8.00 per 1000.

THE RECORD MANUFACTURING COMPANY'S SAPHILE.

The present price of the covers shown above is 7 cts. each, for less than 100. In complete packages of 100, just as they come from the factory, \$6.00. A sample can be sent by mail, at an additional expense of 10 cts. Prices of pails, 1X tin, per 100, 10 qt., \$17.00; 12 qt., \$18.00; 1 C tin, \$15 and \$16, respectively.

This cover has a cap, or hood, that covers the spout entirely; and at the same time the whole arrangement is, by an ingenious device, attached to any pail in an instant. The attachment is such that the cover is hinged so that it will open as shown in the cut.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, OHIO.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, FEB. 1, 1889.

I will delight myself in thy statutes: I will not forget thy word.—Ps. 119: 16.

THE QUINBY SMOKER IMPROVED.

W. E. CLARK, of Oriskany, N. Y., has sent us one of the latest Quinby, or L. C. Root smokers. The improvement consists in having the nozzle hinged by a suitable light malleable casting so that the operation of replenishing can be greatly facilitated. One of our objections to the hot-blast smokers has been the loose nozzles, and the bother of removing and putting them on when they are "all-fired hot." A hinged nozzle can be removed and replaced by a light tap of the fingers. For further information, write the address as above.

OUT-APARIES.

WITH this number we publish the first one of a series of articles on the subject as above, from the pen of one who has had a large experience—Dr. C. C. Miller. They will be continued through a number of issues. While they are designed primarily to instruct those who have little or no practical knowledge of the subject, and who, perhaps, seek such information, they doubtless will contain considerable value for those who have already had some practical experience along this line. If you are not a subscriber, enroll your name at once. This is an important theme, and you can not afford to lose the benefit of these articles.

We have at this date, 8390 subscribers.

NEW ADVERTISEMENTS.

AN unexpected crowd of new advertisements has obliged us to go to press, omitting much valuable matter that should have appeared in this issue. In our next we shall give you an extra eight pages.

LENDING GLEANINGS.

I THINK I have heard publishers find fault because some people borrow the paper and do not subscribe; but I rather like the idea of lending papers. Of course, there may be such a thing as carrying it too far, like borrowing the paper regularly each issue. But to encourage the friends in being neighborly with their copies of GLEANINGS, we shall be glad to have you lend them—that is, after you have read them; and whenever one is lost or soiled, just send us word and we will send you a nice clean one free of charge. We can do this just as well as not, because we almost always have surplus copies that get old, and have to be sold for paper-rags, or about the same. In fact, we have got tons of them stacked away in an old out-building now. Therefore, "Do good and lend, hoping for nothing again." I got the above suggestion from our friend Minnie Coulter, on page 62, last issue.

ALFALFA AND CUCUMBER HONEY.

C. C. MILLER, while in Pueblo, Col., purchased a sample of alfalfa honey of that region. On his arrival home at Marengo, Ill., he sent us this honey, together with a sample of cucumber honey. The flavor of the alfalfa is fully equal to clover, which it resembles closely. It is seldom that we take more than a good taste of honey sent as a sample; but after A. I. R. had tasted, E. R. R. and J. T. C. followed suit. With an expression of "That's good," we kept on scooping it up with our knife-blades until—well, there is just a little left for you to try. The fact that this plant yields from three to four crops of hay in a season, that it will grow in most Northern localities, together with the fact that it yields a superb honey, are no small recommendations in its favor. The flavor of the cucumber could hardly be called first-class, but on the whole it is better than the majority of the second-rate honeys. The taste reminds one a little of cucumber itself, and this becomes more evident a few moments after tasting.

LANGSTROTH ON THE HONEY-BEE, REVISED BY DADANT.

THE new book is finally on our table. It contains 521 pages, while Langstroth's old edition has only 387; and after turning over the leaves for perhaps half an hour (it came just as we were ready to go to press) I should say it gives the fullest and most comprehensive view of bee culture, up to the present day, of anything in print. The book is full from beginning to end of the finest engravings that ever graced any book on bee culture, or any other industry, for that matter. It is not devoted to any particular hive nor system of management, as is our own A B C book, but it mentions all the principal hives and methods in use, and at the same time friend Dadant indicates plainly his preference. I was very glad indeed to find, at the close of the chapter on "Hives," several pages devoted to "the hive we prefer;" and then he gives his reasons for his preference. Everybody is given full credit, so far as I can discover, for their own ideas and for their own inventions, and the book gives one an ex-

ceedingly pleasant idea of the friendly relations in which bee-keepers stand, the one to the other. There is not a word of discussion in it anywhere, that I know of, as to *who* invented this, that, and the other, or to whom credit belongs; and if our friends *have* here and there made a mistake or two in giving credit, I hope no one will be critical enough to take it up. We can send the book by mail, postpaid, for \$2.00; by freight or express with other goods, \$1.85. We have a few of Langstroth's old edition, which we will close out at 50 cts. less than the above, to those who may want one.

SPECIAL NOTICES.

WAX RENDERED BY THE SOLAR WAX-EXTRACTOR.

At the present time our regular advertised price for wax is 20 cts.; 25 cts. in trade. Now, for wax rendered by the solar wax-extractor—clean yellow wax with no impurities on the bottom of the cakes, we will pay 5 cts. more than the above prices. We think it is no more than fair and just, in consideration of the great superiority of sun rendered wax.

A NEW TEN-INCH FOUNDATION MILL FOR SALE.

This mill is one of our latest make, and has just reached its destination. Our customer finds that it requires more wax to dip from than he was prepared for, and now has changed his mind, and concluded to buy his foundation. The mill has never been taken out of the box. If any one in the West is contemplating buying one it will be considerable saving in freight to take this. The outfit, at catalogue prices, would be worth \$23; but we will sell it for \$22.00.

DARK-COLORED FOUNDATION.

Some time ago we advertised foundation, made of dark-colored wax, for 3 cts. less per lb.; but as the demand was constantly greater than the supply, we took the notice out. During the past year, however, we have saved up perhaps a ton, too dark in color to send out as regular foundation; but in my opinion it is exactly as good, in every respect, for brood-combs; but as it does not look quite so nice, we will furnish it, while the supply lasts, for 3 cts. per lb. less than the regular price. Perhaps it will be well to order soon if you want it.

FREIGHTS TO CALIFORNIA.

We find on investigation, that the rates of freight from here to California, on sections and bee-hive material in the flat, differ widely whether you take a carload or less than a carload. The rate from here to San Diego, Los Angeles, or Bakersfield, on a carload, is \$1.25 per 100; while if less than a carload is taken, \$2.90 is charged. In view of this fact, it will be greatly to your advantage if you all could club together in sending your orders, in regard to making up a carload, even if part of the load would have to be reshipped after it got there. Remember, this rate applies to fourth-class freight, under which head comes section boxes, and bee-hive material in the flat which can be called "box stuff." Material coming under a higher classification requires a higher rate.

ALSIKE CLOVER AWAY UP.

One of the largest dealers in seeds in the city of New York has just written us that the very best he can do on prime alsike at present is \$8.50 per bushel; and as this is the very price that we have been advertising it at retail of late, it leaves us in a rather bad predicament; but I rather enjoy it, after all. Do you know why? It is because bee-keepers who have alsike to dispose of are going to get a good price for it; and every bee-keeper ought to have some alsike clover seed to sell; in fact, raising alsike, buckwheat, rape, and seeds, that produce both grain and honey, should be a part of every bee-keeper's business. Now, then, those of you who have alsike to spare will please tell how much you have, and what you will take for it. Of course, we can not pay \$8.50, and furnish bags, and sell it out at retail for \$8.50. Another thing, most of the alsike we sell has to go through that new-fangled fanning-mill that goes by steam power, to make it

Wants or Exchange Department.

Notices will be inserted under this head at one-half our usual rates. All ads intended for this department must not exceed 6 lines, and you must say you want your ad in this department, or we will not be responsible for any error. You can have the notice as many lines as you please; but all over five lines will cost you according to our regular rates. This department is intended only for bona-fide exchanges. Exchanges for cash or for price lists, or notices offering articles for sale can not be inserted under this head. For such our regular rates of 20 cts. a line will be charged, and they will be put with the regular advertisements.

WANTED.—To exchange for extracted honey, a 10 h. p. horizontal engine, worth \$200. I will give somebody a rare bargain. Speak quick.
15tfdb C. H. SMITH, Pittsfield, Mass.

WANTED.—To exchange one of Livingston's farm feed, or grist mills, for hand or power, as good as new, for Barnes foot-power saw.
2-3-4d H. L. FISHER, Milford, Kos. Co., Ind.

WANTED.—To exchange 250 colonies of bees, for horses, mules, wagons, buggies, and 4 h. p. engine, or any thing useful on a plantation.
21tfdb ANTHONY OPP, Helena, Phillips Co., Ark.

WANTED.—To exchange a Barnes foot-power saw, combined circular and scroll, for a foundation-mill, 10-inch, A. I. Root's preferred.
3d MATHEW DODDS, Sauk Center, Stearns Co., Minn.

WANTED.—To exchange buzz-saw for power (not foot-power), 4 saws, 8 to 16 inch, all good as new. Also a few P. R. chicks, fine, warranted.
3d C. E. HATCH, Kentland, Newton Co., Ind.

WANTED.—To exchange bees in Simplicity hives, or History of Civilization, in four volumes, cost \$14.00, for B-flat clarinet.
3d PHIL FISHER, Hannibal, Monroe Co., O.

WANTED.—To exchange pure Brown Leghorn eggs and cockerels (Todd strain) for any thing useful. Write first.
31tdb A. F. BRIGHT, Mazeppa, Wabasha Co., Minn.

WANTED.—To exchange Turner raspberry-plant, for improved poultry eggs or bee-supplies, or fine pig.
3-4d G. F. TYLER, Honey Grove, Fannin Co., Tex.

WANTED.—To exchange about 200 hives, to hold 4 L. frames, for queen-rearing, well painted, nearly new, for any thing useful. I will give any one a bargain.
3d C. D. DUVAL, Spencerville, Mont. Co., Md.

WANTED.—To exchange bee-supplies for a few thousand strawberry plants—Crescent and Sharpless.
3-14db W. E. CLARK, Oriskany, Oneida Co., N. Y.

WANTED.—To exchange volumes of the *American Bee Journal* and *GLEANINGS* for Japanese buckwheat, alsike, or mammoth red clover, or something else.
3d J. W. BARLOW, Burlington, Des Moines Co., Iowa.

WANTED.—Situation with some supply-dealer, apiarist, or honey-merchant, by a single man of 27, eleven years' experience; best of references. Distance no objection. Address
3d A. B. C., Groesbeck, Ohio.

WANTED.—To exchange a new 8x12 self-inking Monumental press, with a lot of type, cases, etc.; one 240-egg self-regulating incubator; one Monarch brooder, for 200 chicks; one brooder for 100 chicks, for 2 or 3 H. P. boiler and engine, section machine, cigar-box planer, honey, alsike clover seed, or offers.
3-4d J. T. FLETCHER, Clarion, Clarion Co., Pa.

WANTED.—To exchange a lot of Turner and Crimson Beauty raspberry-plants for other nursery stock, Italian queens, sections, eggs for hatching, etc. Write first.
3-4d E. R. MILLER, Garden City, Cass Co., Mo.

WANTED.—A good bee-man for an opening, Christian man preferred.
3d C. J. JOST, Banning, San Ber. Co., Cal.

WANTED.—To exchange Italian bees for timber or a "Springfield roadster."
31tdv L. HEINE, Bellmore, Queens Co., N. Y.

WANTED.—To sell or exchange, Italian bees and queens, and supplies. Address
OTTO KLEINOW, No. 150 Military Ave., Detroit, Mich.

WANTED.—You to send for my new price list of Imported and American Italian queens. Can ship as early as the earliest.
31tdb R. H. CAMPBELL, Madison, Morgan Co., Ga.

WANTED.—To exchange one well-drill, good as new, made in Aurora, Ill., cost \$450; will value at \$200, and exchange for bees or any kind of bee-supplies. This is a rare bargain. Address
S. RAY HOLBERT, Watson, Marion Co., W. Va.

WANTED.—As many Italian or hybrid bees as I can get for \$100, delivered here between May 1st and 10th. Who will give me the best bargain?
3d N. E. DOANE, Breckenridge, Gratiot Co., Mich.

WANTED.—To exchange 160 acres of fine land near Watertown, Dakota, for property in some good location for bee-keeping, or would take stock if not too far from here, or an apiary, in part payment, or offers.
3-4d J. L. COLE, Carlton Center, Barry Co., Mich.

SEND FOR HEDDON'S CIRCULARS. Address JAMES HEDDON DOWAGIAC, MICH.

3-4d In responding to this advertisement mention GLEANINGS.

NEARLY THIRTY TONS —OF— DADANT'S FOUNDATION SOLD IN 1887.

It is kept for sale by Messrs. T. G. Newman & Son, Chicago, Ill.; C. F. Muth, Cincinnati, O.; Jas. Heddon, Dowagiac, Mich.; F. L. Dougherty, Indianapolis, Ind.; B. J. Miller & Co., Nappanee, Ind.; E. S. Armstrong, Jerseyville, Ill.; E. Kretschmer, Coburg, Iowa; P. L. Viallon, Bayou Goula, La.; M. J. Dickason, Hiawatha, Kansas; J. W. Porter, Charlottesville, Albemarle Co., Va.; E. R. Newcomb, Pleasant Valley, Dutchess Co., N. Y.; D. A. Fuller, Cherry Valley, Ill.; J. B. Mason & Sons, Mechanic Falls, Maine; G. L. Tinker, New Philadelphia, O.; Jos. Nysewander, Des Moines, Ia.; C. H. Green, Waukesha, Wis.; G. B. Lewis & Co., Watertown, Wisconsin; J. Mattoon, Arwata, Ohio; Oliver Foster, Mt. Vernon, Iowa; C. Hertel, Freeburg, Illinois; Geo. E. Hilton, Fremont, Mich.; J. M. Clark & Co., 1409 15th St., Denver, Colo.; Goodell & Woodworth Mfg. Co., Rock Falls, Ill.; J. A. Roberts, Edgar, Neb.; E. L. Gould & Co., Brantford, Ontario, Canada; J. N. Heater, Columbus, Neb., and numerous other dealers.

Write for free samples, and price list of bee supplies. We guarantee every inch of our foundation equal to sample in every respect. Every one who buys it is pleased with it.

Notices will be inserted under this head at one-half our usual rates. All ads intended for this department must not exceed 6 lines, and you must say you want your ad. In this department, or we will not be responsible for any error. You can have the notice as many lines as you please; but all over five lines will cost you according to our regular rates. This department is intended only for bona-fide exchanges. Exchanges for cash or for price lists, or notices offering articles for sale can not be inserted under this head. For such our regular rates of 30 cts. a line will be charged, and they will be put with the regular advertisements.

WANTED.—To exchange for extracted honey, a 10 h. p. horizontal engine, worth \$200. I will give somebody a rare bargain. Speak quick.
15tdfb C. H. SMITH, Pittsfield, Mass.

WANTED.—To exchange one of Livingston's farm feed, or grist mills, for hand or power, as good as new, for Barnes foot-power saw.
2-3-4d H. L. FISHER, Milford, Kos. Co., Ind.

WANTED.—To exchange 250 colonies of bees, for horses, mules, wagons, buggies, and 4 h. p. engine, or any thing useful on a plantation.
21tdfb ANTHONY OPP, Helena, Phillips Co., Ark.

WANTED.—To exchange pure Brown Leghorn eggs and cockerels (Todd strain) for any thing useful. Write first.
3ftdb A. F. BRIGHT, Mazeppa, Wabasha Co., Minn.

WANTED.—Two students for the coming season.
GEO. E. HILTON, Fremont, Mich. 4-5d

WANTED.—To exchange Turner raspberry-plant, for improved poultry eggs or bee-supplies, or fine pig.
3-4d G. F. TYLER, Honey Grove, Fannin Co., Tex.

WANTED.—To exchange a new 8x12 self-inking Monumental press, with a lot of type, cases, etc.; one 240-egg self-regulating incubator; one Monarch brooder, for 200 chicks; one brooder for 100 chicks, for 2 or 3 H. P. boiler and engine, section machine, cigar-box planer, honey, alsike clover seed, or offers.
3-4d J. T. FLETCHER, Clarion, Clarion Co., Pa.

WANTED.—To exchange a lot of Turner and Crimson Beauty raspberry-plants for other nursery stock, Italian queens, sections, eggs for hatching, etc. Write first.
3-4d E. R. MILLER, Garden City, Cass Co., Mo.

WANTED.—To exchange one well-drill, good as new, made in Aurora, Ill., cost \$450; will value at \$200, and exchange for bees or any kind of bee-supplies. This is a rare bargain. Address
3-4d S. RAY HOLBERT, Watson, Marion Co., W. Va.

WANTED.—To exchange a Webster's Unabridged Dictionary for extracted honey or bees, with some one not too far distant. JOHN A. GEETING, 4d McKeesport, Pa.

WANTED.—You to send for my new price list of Imported and American Italian queens. Can ship as early as the earliest. R. H. CAMPBELL, 3ftdb Madison, Morgan Co., Ga.

WANTED.—You to send for my illustrated Price List of supplies; Bees, Queens, etc. 4-5d GEO. E. HILTON, Fremont, Mich.

WANTED.—To exchange 160 acres of fine land near Watertown, Dakota, for property in some good location for bee-keeping, or would take stock if not too far from here, or an apiary, in part payment, or offers.
3-4d J. L. COLE, Carlton Center, Barry Co., Mich.

WANTED.—To exchange for honey or offers, about 25 colonies of Italian bees, in new, movable-frame hives, frames 9½x12¾ inside measure; 8 frames to the hive; also one second-hand Barnes foot-power combined saw.
CHAS. DOREMAN, Pittsburg, Tex.

WANTED.—To exchange one American Incubator, 250-egg capacity, about 50 nuclei, 2, 3, and 4 frame, 20 cts. each, about 50 Simplicity hives, 10 frame, \$1.00 each, for horse-power, corn-grinder, or any thing useful to a farmer. GEO. W. BAKER, 4-5d Milton, Wayne Co., Ind.

WANTED.—To exchange, house and lot with grapevine apiary of 50 colonies, Italio-Carniolans. Good location, and a good property, at a bargain. Also want to buy or rent an apiary in good location. JNO. C. CAPEHART, St. Albans, W. Va.

WANTED.—To exchange one Jones wax-extractor, or 275 side-opening sections, 375 ¼-lb. sections, 500 separators for Heddon case, 20 Simplicity hives, one Lamb knitting-machine, 50 Jones honey-cans, 5 lb.; 200 Concord grapevines, for 20 to 24 inch circular saw, type-writer, bicycle, camera, bees, or supplies. J. A. GREEN, Dayton, LaSalle Co., Ill. 4d

WANTED.—To exchange Italian bees for timber or a "Springfield roadster." L. HEINE, 3ftdb Bellmore, Queens Co., N. Y.

WANTED.—Bee-keepers in Missouri, Kansas, Nebraska, and Arkansas to learn something of value by addressing Rev. E. T. Abbott, St. Joe, Mo. 4-5

WANTED! Bee-Help. Will engage on favorable terms two young men, desirous of learning practical apiculture. None but strictly temperate need apply.
4-7d S. I. FREEBORN, Ithaca, Wis.

WANTED.—Correspondence with parties having Japanese buckwheat to sell, or exchange for supplies. JOS. NYSEWANDER, Des Moines, Ia. 4d

WANTED.—Situation in an apiary for the season of 1889, from 6 months to a term of years.
4-5d S. W. WHITE, Liberty, Clay Co., Mo.

WANTED.—To exchange one cutter-head, one dovetailing mandrel with saws, one six-inch rubber-belt, 30 ft. long; 50 ft. of three-inch rubber-belt, all as good as new, for bees or bee-keepers' supplies; also one six-inch Pelham fdn. mill. 4ftdb THOMAS GEDYE, Kangley, LaSalle Co., Ill.

WANTED.—To sell or exchange, Italian bees and queens, and supplies. Address
OTTO KLEINOW, No. 150 Military Ave., Detroit, Mich.

1889. Italian Queens. 1889.
For \$1.00 From Jan. till June.

HONEY COLUMN.

CITY MARKETS.

CINCINNATI.—Honey.—Prices are about the same as quoted last; but the demand from manufacturers is improving. We quote: Extracted honey at 5@8 on arrival. Prices of comb honey are nominal, at 12@16 in the jobbing way. *Beeswax.*—There is a good demand, which brings 20@22 on arrival, for good to choice yellow.

Feb. 12.

CHAS. F. MUTH & SON,
Cincinnati, Ohio.

St. Louis.—Honey.—The supply of honey is not large, but it is moving very slow. Choice comb honey is selling at 13@14; fair, 11@12; dark and broken, 8@10. Extracted, dark, in bbls., 4½@5; choice, 5½@6. In cans, dark, 5@5½; fair, 6@6½; choice, 7@8; fancy, 9. *Beeswax.* prime, 20. The outlook on honey is not very bright.

Feb. 9.

W. B. WESTCOTT & Co., St. Louis Mo.

KANSAS CITY.—Honey.—We quote: 1-lb. comb, white, 16; fall, 14; California white, 16; 2-lb. California white, 14; 2-lb. extra Cal'a, 13. Extracted, Cal'a white, 8; Cal'a amber, 7. *Beeswax.* 20@22.

CLEMONS, CLOON & Co.,
Kansas City, Mo.

Feb. 9.

CHICAGO.—Honey.—The supply of choice grades is light, and the prices are held at about 17; but sales are small. The off grades are moving very slowly, at lower figures. Extracted brings 7@8 for white and medium grades. *Beeswax.* 22.

Feb. 8.

R. A. BURNETT,
Chicago, Ill.

DETROIT.—Honey.—Best white comb in one-pound sections, 16@17 cents. Sales slow. Extracted, 9@10. *Beeswax.* 22@23.

Bell Branch, Mich., Feb. 11.

M. H. HUNT.

St. Louis.—Honey.—No material change in the market. Too much mild weather for good honey-trade. *Beeswax.* 20.

Feb. 9.

D. G. TUTT GRO. CO.,
St. Louis, Mo.

CLEVELAND.—Honey.—Market very dull and quiet. Very little No. 1 white in market. Price ranging from 15@18c.

Feb. 13.

A. C. KENDEL,
Cleveland, O.

FOR SALE.—I have a quantity of extracted honey in 50-lb. kegs, which I will sell at the following prices: 8c for the white and 7c for the amber, f. o. b. The honey is first-class. *C. H. STORDOCK,*
Durand, Ill.

tries of the Universal Postal Union, 18
cts. per year extra. To all countries
not of the U. P. U., 42 cts. per year extra.

OUT-APIARIES. NO. II.

CHOOSING A LOCATION.

AFTER deciding to have an out-apiary, you must decide on a location. It is quite likely that local circumstances will have a good deal to do in deciding. Some relative or friend may live somewhere near the proper distance, and I would not hesitate to have an apiary half a mile further or nearer, for the sake of being at a place where the people were pleasant to get along with. My first out-apiary was located at my father-in-law's, although it was a mile nearer than at that time I thought right. The second was reached by a roundabout way which makes me travel a mile or more extra, but a very pleasant relative lives there. The third was chosen mainly without reference to the people; and as the plan then taken in choosing was about the one I should in general advise, I will tell how it was done. One day, some time before I wanted to occupy the site, when we had plenty of time for a pleasant ride I took my wife and her sister in the buggy to prospect. I wanted them along because we three were the whole working force, and they were as much interested as I; and, besides, we would enjoy the ride. I knew about the direction, and something of the distance I wanted to go, so we rode along, discussing the different places as we came to them. "That place wouldn't do, for there isn't a spot where we could be in the shade, and we don't want to work in the hot sun." "There's a nice little grove, but it's too far from the house, and thieves would be likely to feel more free at such a distance from the house." "Those apple-trees would do nicely, only they are very close to the road, and we should be in plain sight of every one passing, which isn't so pleasant as being a little more private, and, besides, I suspect there would be more temptation to meddle with them at night, if some

meddler should see them so very plainly every time he passed by."

One or the other of the above objections lay in more or less force against all the places on the straight road and upon the side-roads until we came to one where was quite an evergreen grove right in front of the house, a hedge between one end of it and the road, so that we should be reasonably near the house, in a dense shade (too dense, I think), right close by the road, but entirely screened from it by the evergreen hedge. It was by odds the best place of all we had seen. The farmer was one with whom I had scarcely any acquaintance, but for many years I had known him by reputation as an upright man, and, moreover, I was strongly impressed in his favor from the fact that two sons who had been to school to me years before were manly, trustworthy fellows. So I drove up to the door.

"How do you do, Mr. Belden? I have too many bees at home, and I want to find a place to put some. What is the chance of my bringing some here?"

He replied, laughingly, "Oh! I couldn't have any bees here. They'd sting me every time I tried to do any thing with them."

"But," said I, "I don't want you to do any thing with them. We'll take all the care of them. All I ask of you is to let them stay here."

"Oh! if that's the way, bring on all you like, and welcome."

"And how much shall I pay you for rent and for trouble?"

"Oh! nothing at all."

And no insisting made any difference.

I want to press pretty strongly the matter of having nice people where you have an out-apiary. If things are unpleasant, you can't pick up and leave at a moment's warning, and it is in the power of your landlord to make it uncomfortable for you in

a good many ways. Little annoyances of which you can hardly complain may make every visit to be dreaded; whereas, with the right people, and the right behavior on *your part*, every visit will be anticipated with pleasure on both sides.

You may happen on a location otherwise suitable, only that it may be used as a pasture for farm stock, as many orchards are. Beyond the occasional displacing of a hive, I never knew any harm to come from this; and E. France says, "All five of our out-apiaries are used by owners of the land for pasture for farm stock, horses, cattle, pigs, sheep, etc., including poultry."

Marengo, Ill.

C. C. MILLER.

Friend M., may I suggest the importance of being "nice people" yourself? and, in fact, I do not believe that anybody ought to think of starting out-apiaries unless they are of the class that "thinketh no evil," "suffer long," etc.

HOW TO SELL HONEY, AND HOW TO MAKE MONEY.

VALUABLE SUGGESTIONS TO PRODUCERS.

IN my last letter to GLEANINGS I promised to write an article on the above subject. What I shall say at this time will refer to making sales direct to consumers. As I have succeeded so well in this, it may be due me to say that, whatever I may write on this subject, can not but be an advantage to many.

Here, we are not often blessed with good crops of honey; but even in seasons of bountiful yields, when choice comb honey is offered at 12½ cts. per lb., and 11 lbs. of finest extracted given for \$1.00, I never had to sell *my* honey at such low figures.

When seasons do occur where large crops of surplus have been secured, it is bad policy to force it all on the market the same year at unpaying prices, as it is altogether probable that the crop will be a light one the succeeding year. It is true, that comb honey looks its best when new, and should find a market at the earliest opportunity; but *extracted* honey, when properly cared for, will keep perfectly for years. If the price will not justify this year, it is sure to do so another. Here let us score one more point in favor of extracted honey; and so long as I can sell it at the same price I can get for honey in the comb, I'll keep on scoring points in its favor. I shall produce but little more comb honey; and as my purchases of honey in this shape generally result in loss from breakage by careless handling of the transportation companies, I have decided to have no more shipped to me at my own risk.

It may be urged, that it requires more time and greater effort to sell liquid honey. I think not; but even if this is true, it is a good thing. I can make twice the money producing it, or on that which I purchase, that I can on comb honey. The majority of those who make a specialty of producing honey have ample time to devote to making sales of their honey during the fall and winters, which time they would be glad to have profitably employed. Why, this unoccupied time is the chief trouble to many of the craft; then why not employ profitably to ourselves this time in selling our product at paying prices, direct to consumers, rather than suffer that which justly belongs to us to go into the hands

of speculators who may not—often do not—pay the shipper any thing? I have strong suspicions—judging from a complaint that was made recently in one of our bee-journals—that several barrels of honey which I bought of a certain commission dealer was obtained from a bee-keeper who received no pay for his honey.

Having secured a crop of honey, remuneration for toil depends entirely on the price the apiarist obtains from it. To those who have hitherto sold their honey at prices which have failed to satisfy you, I will now offer a few hints on "how to sell honey."

The great crop of honey obtained in 1886 filled this country to overflowing, and the bottom fell clear out of prices, as you all know. Well, I got out all right, and made money. I started a peddling wagon, driving through the country, selling to farmers and villagers, and my honey was all gone at good prices, almost before I was aware of it. This season I had no surplus, but have bought tons and tons of it at low enough figures, from dealers to whom some good bee-keepers had sent it for a "big price." Some changes have been made in my tactics this season; and as they have pleased me, I will give them to the reader. I have two sons, aged 17 and 19 respectively. These young fellows have learned how to sell honey too. Provided with order-books and samples of honey in small glass jars, they are ready to solicit orders in any town or city. Taking streets in regular order, every family is offered an opportunity to buy. Usually a few names of the first families of the town are secured, which serve well as leaders.

It is surprising, when these names are shown, how readily others fall in line with *their orders*. When a town is to be worked for the first time, the boys will say, "Papa, you had better tackle that place, as you can work the racket on 'em better than we can."

To become an expert in the art of selling liquid honey, tact, as well as experience, plays an important part. One must not talk as a drummer fresh from a commercial house would, but just as a farmer having a little honey to sell. Success in making sales depends largely on the manner of presenting the case. As a help, I will give an example.

Should the lady of the house answer our call, we would, with some dignity and a pleasantness of manner, bid her the time of day. At once the impression is made that a gentleman, not a tramp, is present, and an invitation is given to "come in." This is what we want, as it gives us an opportunity to become somewhat acquainted with our customer; and then we can give the *baby and all* a taste of honey, which is sure to get the children to say, "Mamma, do buy some, it's so nice." At this juncture we say, "Oh, yes! you see" (exhibiting the long list of names on the order-book) "nearly all the folks in town are giving me orders." This will generally "bring down the house;" but if the case requires more talking, we fill in the chinks by explaining the medicinal qualities of honey—how good it is for colds, coughs, often saving doctors' bills, etc. If this doesn't do the work, you'd better waste no more time. We never take orders for less than one dollar's worth, as we find it doesn't pay.

When orders for a few thousand pounds have been taken, we begin at the starting-point to deliver. If roads are good, and distance not too great,

our team is sent with the honey, and necessary appliances for rapid delivery; otherwise we ship to destination, hiring a team to make deliveries. As a rule, honey is taken for use of team, boarding, lodging, etc. We carry about all the honey in 60-lb. tin cans, screw caps, two in a case. One case is made large enough to admit, when cans are raised tip, an oil-stove under them, that honey may be kept thinned, so it may be quickly run into the retailing-can, which holds 150 lbs., with gate soldered firmly, and this can is also raised in its case so that vessels may go under the gate, and an oil stove beneath the can. With this arrangement the honey is made to run out at once. Without this we could not get along in cold weather. We always take 50 to 100 lbs. more honey along than our orders call for; but even then, seldom have any to carry back.

Now, I am aware that many will say, after all. "Oh! I can never go to all this trouble to sell my honey; it won't pay me. I'll just do as I have been doing—ship my honey to some dealer, and let him sell it for me." Well, then, all right; do so, and I will get some of it cheap, and make the profit you lose—that is all.

I made a clear profit, in one day's sales, this fall, of \$26.00 on honey which some of you bee-keepers shipped to a commission man, and the price I paid for the honey may have satisfied the bee-keeper who produced it too. The least pay I have had selling direct to consumers this fall and winter was \$5.00 a day. Did my health permit any thing like constant work in the business, I would ask for nothing better.

Before closing I wish to say that I know there are many apiarists so located that their honey *must* be shipped to distant markets; but where there is any thing like a home market, use it, and use it well.

J. A. BUCHANAN.

Holiday's Cove, W. Va., Jan. 23, 1889.

Friend B., I presume you well remember that, about the time GLEANINGS was started, and for several years afterward, I was perhaps the strongest and most earnest champion of extracted honey, and it was with great reluctance that I finally gave way so far as to agree that comb might be almost as profitable, all things considered. I do believe you are right in regard to selling honey—that is, if the man who produces it has unoccupied time on his hands; and if he has not, I am inclined to think that he can hunt up some one who will dispose of his honey in the way you mention, to a good deal more profit than sending it to commission houses. Circumstances, however, may alter cases. A commission man who loves his business, and loves his customers' interests, as well as his own, would be a good deal in the line of somebody taking up the kind of work you describe. I also like the idea of taking a sample of the honey around first, and taking orders before delivering. The Moore brothers, whom we have mentioned once or twice before, have been for years doing this same kind of business; and they take great cities like Toledo and Cleveland, and canvass them thoroughly. For the first time this winter we have been selling not only honey, but the produce of our market garden, in just that way. The mild weather has made the roads so bad that it seemed too bad to ask a horse

to lug heavy vegetables around through the mud, before we knew where they were to be delivered; therefore the boys go out in the morning first and take orders just as you have described. If they sell enough to warrant taking a horse, then a horse is used; but a good deal of the time they use a couple of our light wheelbarrows, and get along quicker than even a horse. When there is sleighing they use light sleds, with a light box. In this way our fruit and vegetable rooms and cellars can be always kept orderly. The one who takes the orders goes and puts up in neat packages just what he wants and no more. The fruit and vegetables are not bruised by being bumped around in a wagon, and the honey is not mashed and soiled. Packages are handed to the purchaser, clean and tidy. We visit our customers every other day. The onions and lettuce and radishes—yes, and spinach too—can grow in our cold greenhouses until they are wanted, so we have no wilting and no stale goods on hand.—The picture you give us, of a father working side by side with his boys, is indeed a pleasant one; and although you do not mention it, friend B., I suppose that you and your boys have learned how unprofitable it is to have quarrels or any thing the least unpleasant with the people you call upon. One who goes from house to house needs not only tact but gentility. The suggestions you give us are very valuable.

CELLAR WINTERING.

SOME POINTS WELL TAKEN BY GEO. E. HILTON.

AS I am laid up for repairs with rheumatism, I have thoroughly digested GLEANINGS for Jan. 15, and will say a few words in conclusion.

CELLAR WINTERING VS. OUTDOOR WINTERING IN CHAFF HIVES.

For three winters I have been experimenting with a cellar above ground. The walls are 26 inches thick, 24 inches of which are sawdust, two inches air space, and then lathed and plastered inside. There is a cement floor. The only ventilation it has is a 5-inch pipe about the center, running within 2 inches of the cement floor. I have put in about 40 colonies each winter, a few in single-walled hives, the remainder in chaff hives, packed the same as outdoors, only the cover is removed. The cellar is 10x24x6 ft. high. They have wintered successfully every winter, only not as dry and bright as outdoors. My preference is chaff hives and outdoor wintering.

SECURING AN EXCLUSIVE LOCALITY, ETC.

I can hardly agree with you and friend Dilworth in regard to "exclusive right of territory." In the first place, I do not think it would be right; and in the second place I don't think it possible. I doubt very much your ability to find a community where *all* could be bought; and he of whom you could not purchase the agreement not to keep or allow bees to be kept on his premises would either keep or lease to some one else who would pasture the other fields you had purchased the right of, and what redress would you have? I see no other way than to let all try it who want to, and then let the "survival of the fittest" have the pasturage. A few

more seasons like the past two, and all survivors will have all the pasturage they need.

STORES FOR WINTER; LARGE CONSUMPTION — SEE QUESTION 102.

"Which is the more profitable—colonies that require from 20 to 25 lbs. to carry them through, or those that will get along on from 5 to 10 pounds?" Most decidedly, the former; and could I get them to use up another 10 lbs. between April 15 and June 1, I should consider it a good investment in this latitude. An extra 10 pounds of old fall honey means 25 lbs. of white clover, if it is in the fields. My bees go into winter quarters with nearer 40 lbs. than any thing else, and I have not only been successful in wintering, but in a good surplus also.

NOTES OF TRAVEL.

They are very interesting indeed. I am glad to hear friend Perrine has risen above his losses in the interest of apiculture, and of that wonderful ranch of our good friend David C. Cook. May God spare him yet many years of usefulness, as well as yourself, is my prayer.

GEO. E. HILTON.

Fremont, Mich.

I am glad to see so favorable a report for chaff hives and outdoor wintering, away up in the northern part of Michigan. In regard to bees and neighbors, I should like to have some of the friends try it and report. Go out and canvass your neighborhoods, and see what it will cost you to get a promise from each land-owner to agree not to keep bees, say for the next five years.

GIVING BEES WATER WHILE IN THE CELLAR.

ANSWERS TO PRACTICAL QUESTIONS.

A SUBSCRIBER to GLEANINGS propounds the following question: "Do bees in the cellar during winter need water? and if so, how is it given?" Bees that are wintering properly need no water, for, inasmuch as no brood is reared in the cellar, of any amount, they would have no use for it, even should they take it. As far as my experience goes, water is used by bees only during the time there is brood in the hive. Out of the colonies which I winter in the cellar, not one in ten have any brood, except a few eggs, when the bees are set from the cellar, whether the time of setting from the cellar be March 15th or May 1st. The year I kept the cellar warm with the oil-stove, brood-rearing was carried on to quite a large extent, so that the bees were very uneasy; and to see what effect water had on them I gave some to a few in a sponge at the entrance. This seemed to make those colonies more quiet; but as all eventually died, I do not know whether it was any benefit to them or not. One or two that brooded quite largely had enameled cloth over them; and although considerably weakened when set out in the spring they came out so as to finally make quite good colonies. These were more quiet than any of the rest, and I laid it to their getting water from the condensed moisture on the under side of the cloth. All know that moisture will so condense on these sheets as to form large drops, which is a great injury to weak and feeble colonies, by its dropping on the bees and making them so wet that they finally perish. However, I do not think it is best for bees to breed in the cellar, hence say that water is not necessary.

FRAMES FILLED WITH BROOD.

The same subscriber wishes to know how I compel bees to fill the brood-combs with brood in advance of the honey harvest. This is usually done by what is known as "the spreading of the brood." This, in short, is as follows: As early in the season as I think it will answer, or when there is little danger of very frosty nights, the brood which is found in the hive is reversed, by which is meant that the combs which now occupy the center of the brood-nest are placed on the outside, and those which are on the outside are put in the center. This puts the combs having the most as well as the oldest brood on the outside, while the young brood, which usually occupies only a small space in each comb, is placed in the center. This causes the queen to fill these partly filled combs very quickly with eggs—much more so than she otherwise would, so that we make quite an advance over what would have been had they not been disturbed. In a few days more, a comb from the outside of this brood is placed in the center of the brood-nest, which causes the queen to fill this comb quickly; and so on till all of the combs are filled with brood. If all are not quite as full of brood as you would like them, when the honey harvest arrives, reverse the brood-nest again, the same as you did at first, when you will have all of the combs full of brood, where the bees would be likely to store their first honey, thus causing the honey to go into the boxes, as the queen is never crowded with honey from the center of the brood-nest out toward the outside of the hive. The crowding of the queen is done from the bees putting their honey in the tops of the combs and at the sides, and then narrowing down on the brood space. If there are empty combs in the brood-chamber when the harvest arrives, these should be taken away, and the space which is left should be filled with dummies.

THE LATERAL PLAN.

Another correspondent wishes me to tell in GLEANINGS whether he can use wide frames on the lateral plan, "in the Heddon (old style) case, or the Lewis section-holder." Single-tier wide frames, as I use them, are not adapted to cases of any kind. They can be used right on top of any hive, by placing a wide board over them to shed the rain, but I much prefer what is termed a "cap," or "half-story cover," over them. In this way they can be used nicely, but they are especially adapted to chaff hives while using on the lateral plan, or to using on such hives as are placed in large packing-boxes, as is recommended in Hutchinson's book on comb honey. In these there is no limit to the spreading-out of wide frames on the lateral plan; while any one using common reason can see that such wide frames can not be used with any satisfaction in any of the case or super systems now before the public.

TEMPERATURE OF BEE-CAVES.

It would seem by the editor's comments at the foot of my article, that I have not fully made myself understood on all points regarding my bee cellar, or cave. As soon as the bees are out of the cellar in the spring, the doors are all opened wide, as well as all ventilators, in which shape it is left all summer, so as to thoroughly dry out what moisture the walls and earth overhead have absorbed during the winter. This, of course, causes the air inside the cellar to become nearly the same as it is outside. Occasionally I put in some boxes of bees,

when forming nuclei by the "caged bees" plan, which I have given in *GLEANINGS* during years past, when, if the doors are kept closed for two or three days, the temperature goes down to about 60° in July and August. As winter draws near (with the doors wide open), the ground cools off till I have the temperature inside, after the bees are put in, as spoken of in my last. Friend Root seems to be bound to compare these bee-caves with deep caverns in Kentucky and elsewhere, that go hundreds, if not thousands of feet, into the earth. While we call our winter repositories caves, yet if any one will turn to the description which I gave last year of mine, it will be seen that the surface of the roof, together with the sides above the surface of the earth around it, is nearly as great as the sides and bottom which are under ground, properly speaking, thus causing the mean temperature between the warm earth beneath and the cold air above to range from 43° to 46°, as I gave in my last.

Borodino, N. Y., Jan. 25, 1889. G. M. DOOLITTLE.

Prof. Cook experimented quite fully in the matter of giving bees water when kept in cellars, and I believe his decision was that, although bees will take water, and it seems to quiet them for the time, under certain circumstances, the result in the spring shows that colonies supplied with water are not only no better off, but, as a general thing, not as well off. They are more likely to die from dysentery than those that do not have water.—All right, old friend. No doubt I have got natural caves on the brain a little; but I have succeeded in bringing out the point I wanted; namely, that you managed to have your bee-cave quite a little colder than the average temperature of the earth below the frost-line; and this low temperature was secured by letting the severe weather outside affect the cellar to a certain extent in the manner you explain.

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

GARDENING IN FEBRUARY, ETC.; HOW MUCH OF IT CAN WE DO PROFITABLY?

WELL, we can do a good deal. The sun is a good deal higher up, and consequently comes down with much more heat when it shines. If you want to see how rapidly the sun travels northward, just make a mark on the floor (that is, if you have got a south window that the sun shines through so as to strike the floor) where the shade of the top of the window falls. On this mark, write the date. Next day the sun shines, look again and see where the shadow comes. You will be surprised to find that the sun makes a different path every day; and at noontime the marks will be from one to two inches apart, where only a single day intervenes. This is a good study for the children, for it shows them plainly the motion of the earth and of the heavenly bodies.

Your cold-frames, greenhouses, or hot-beds, will now need attention at noon, or the plants may be scorched before you are aware of it. If possible I would have all these structures so you can go inside and consult your thermometer, or, when you get a little used to it, you can tell what tem-

perature the plants need, without a thermometer.

If you are going to raise plants for sale, now is the time to put your Early Jersey Wakefield cabbages into the seed-bed. The cabbage seed and celery seed sown in January should give plants now with the second leaves coming out, and this indicates that they are ready to be transplanted and need more room. During the latter part of February is also the proper time to sow the seed for your early tomato-plants. Every season we have a call for extra-large strong tomato-plants. When we are short, and do not want to spare them all, customers frequently offer a nickel apiece for them, especially when they are set in pots, so the plant can be turned out to show the mat of roots around the ball of earth. Such tomato-plants, at a nickel apiece, will pay tiptop for your time and trouble. Now, if, in addition to this, they are choice expensive varieties, you will probably have a great many customers who will willingly pay a dime apiece for the plants. If the foliage of the tomato itself indicates that it differs from the common kind, this will help call attention to it, and encourage people in wanting just one or two of the "new-fangled kind." Two years ago we sold a good many of the Mikado plants at 10 cents apiece—that is, extra-early and extra-strong plants. A year ago the Dwarf Champion brought a dime each—all we wanted to spare of them, on account of the beautiful dark-green foliage, and the thick stubby appearance of the plant itself. Good strong Ignatum plants will also probably bring 10 cents apiece at retail next May. We have a lot of them planted, and our first planting of Dwarf Champions are already transplanted into little pots. Everybody who sees them says, "Why! aren't they just as cute as can be?" As these little bits of pots now cost only about $\frac{1}{4}$ of a cent apiece, we can readily afford to sell plant and all for a nickel. In addition to offering single plants at high prices, you will need a lot of the plant-boxes described in our book, "What to Do." A little later on, these will sell readily for from 20 to 25 cents, box and all, each box containing one dozen plants. *Extra-strong* celery-plants will readily bring twice as much as ordinary plants; and it is a good plan to have some beautiful White Plume plants on hand to show to customers. Somebody will want them about as soon as they can be put outdoors, and it will pay very well to raise them, even if you do not get more than a cent apiece for them.

DANDELIONS UNDER GLASS.

For some years past, in the East, early dandelions for greens have commanded good prices. Here is something in regard to the matter from our friend who originated the Grand Rapids lettuce:

In your article on "Raising Winter Vegetables," I see you do not mention forced dandelions for greens. As my experience with them may be of some use to you, I give it. Early last spring I sowed $\frac{1}{4}$ lb. of the broad-leaved dandelion in rows one foot apart. They were cultivated, and thinned the same as salsify; were taken up in November, and

the most of them were trenched the same as celery, so as to be handy to get at any time during the winter. The rest of the roots were planted under the greenhouse benches, 4 inches apart each way, in good soil. Six weeks from planting they are ready for market; are about a foot high, of a light green, and the finest greens I ever saw, retailing here at 20 cts. per lb. I have just planted roots for a second crop.

EUGENE DAVIS.

Grand Rapids, Mich., Jan. 21, 1889.

Friend Davis was kind enough to send us a sample basket of the dandelions. They are not only beautifully white and handsome, but they are delicious when cooked in winter time. Physicians have for years past recommended the use of dandelions in the spring. They are cut off a little below the surface of the ground, so that some of the dandelion root comes along with the plant, and it is the root, I believe, that is claimed to possess medical properties. In selling dandelions you might mention this latter point if you think best.

If you have any turnips that have started to grow before you have got ready to use them, just plant them under the benches, as you do pie-plant and dandelions, and they will make an astonishing growth in a very few days. The yellowish-white tops, resembling the Golden Self-blanching celery a good deal in appearance, will be found, when cooked like asparagus, a most delicious dish.

Rhubarb, or pie-plant, can now be grown under the shed described for celery. Just dig up some roots and bury them in rich dirt, watering them occasionally; and if you have a temperature warm enough for the other plants, you will get delicious stalks of rhubarb. It seems to me the nicest pies I ever tasted were made from rhubarb-stalks grown in the greenhouse. If you have raised benches for your plants, under the benches is the place for the rhubarb.

THE GRAND RAPIDS LETTUCE.

As this is the season of the year when the great bulk of the lettuce will be planted in boxes or under glass, for the spring crop, we take pleasure in copying from the *American Garden* for February the following in regard to the Grand Rapids lettuce:

UPRIGHT LETTUCE IN THE GREENHOUSE.

In December, 1887, my attention was called to the culture of tall or open-head lettuce under glass and in the greenhouse. The subject was of greater interest, as I had heard and therefore assumed that it was impossible to raise the tall kind of lettuce under glass. The seeds used by the originator he calls "Grand Rapids" lettuce, and the plant in growth has the appearance of the Perpetual or the Hanson. It is a light green, upright, wrinkled, soft-head lettuce.

In correspondence with Mr. Eugene Davis, the originator of this lettuce, I was enabled in February last to receive by express from his houses heads weighing three-quarters of a pound each of as nice, tender lettuce as one would wish to see. Through his kindness, also, I had a few seeds of the lettuce sent me. Part of these I planted last March. In May they were set in open ground and made good growth; but from those saved for seed I secured but a few pods of seed last August. I planted the rest of the seed received from Mr. Davis in the spring, and the plants were set in the greenhouse in September. In November they had made a healthy growth, weighed about half a pound each, and were sold at the full price of head lettuce growing in the same house. Mr. Davis states that

this lettuce has been raised in that locality for the past ten years. There are about seventy-five greenhouses, 20x50 feet, in Grand Rapids, devoted to the culture of this lettuce exclusively, the product going east to New York, also to Chicago, Cincinnati, and Cleveland, shipped in paper-lined barrels, and sold by the pound at about 19 cents net. The selling by the pound pleases both buyer and seller. The average weight is about three-quarters of a pound to the head, some heads weighing 1½ pounds. The business is remunerative in those markets that receive a tall lettuce. Of course, where a head lettuce is demanded this would not sell.

The houses face the south, running east and west; the front is 3 feet high; the front rafters are 16 feet long, rising beyond the center to the ridge, the highest point, which is 10 feet above the house floor; the back rafters are 8 feet long, resting on a wall 6 feet high on the north side. The width of the houses is 20 feet and the length 50, 60, or 100 feet; 20x50 is safely heated by brick return flues and a wood fire, burning about eight cords of 4-foot wood, costing \$3 a cord, and between September and May yielding two or three crops of lettuce.

The benches were not solid; the dirt is 7 inches deep on boards resting on wooden supports and posts. The flue runs the whole length of the house, and the chimney is over the furnace; temperature can be maintained easily at 65°; the furnace filled at 9 p. m. will last until morning, and is kept going all day in the coldest weather. The 100-foot-long houses have a furnace at each end, 50 feet in length, being all one fire can easily heat.

With me the "Grand Rapids" lettuce proves less liable to rot, but less salable than head lettuce in the winter. Mr. Davis says: "It stands shipping better, and is not so liable to rot on the benches. The trouble with head lettuce with us is, if it gets to top rotting you can't stop it; this kind, the heads being more open, you can stop it at once." He also says: "I tried three kinds of head lettuce last winter, and I find it can not be sold by the pound at a profit to the grower; also when head lettuce gets its growth it must be sold at once; grown by the side of Grand Rapids lettuce it rotted and was not reliable. All who are trying the business here are making a success of it. This lettuce will grow as well in hot-beds as in hot-houses. In regard to weight, profit, etc., I have just finished (March 6, 1888) cutting one house, 20x60, and got 1400 pounds, which nets us 19 cents per pound. It gives better satisfaction sold by the pound. In a good season this lettuce is a heavy seeder. The past season my crop was very light, on account of dry weather."

Mr. Davis is a young man, probably thirty-seven years old, who has devoted sixteen years of study and experiment to the improvement of lettuce, with a view of growing it under glass. He started with the Black-seeded Simpson. He wanted lettuce that would not rot, of rapid growth, light-colored, handsome in appearance, crisp, tender, excellent in flavor, and that could be kept ten days or more without hurting, when ready for market, should the weather be unfavorable for shipping or the market dull. During this time the stock has not got into the hands of seedsmen.

In January, 1888, Mr. A. I. Root, of Medina, Ohio, paid \$50 for half a pound of seed, which is the only case of sale outside of Grand Rapids, where Mr. Davis supplies the seed to all who are in the business in that section. He says he has no seed for sale this year, but could have another season. His experiments have been conducted in his own interest, and not with a view to sell seeds or plants; but the subject is of sufficient importance to warrant continued investigation on the part of those engaged in raising lettuce under glass. I have no personal interests to serve in speaking of the subject. Mr. Davis has, by constant selection and improvement, succeeded in keeping the stock up to its present capabilities, from which it would speedily decline in the hands of a careless operator.

Hampden Co., Mass.

W. H. BULL.

MORE ABOUT THE GRAND RAPIDS LETTUCE; HOW TO CONSTRUCT A GREENHOUSE FOR LETTUCE; HOW TO WARM IT, ETC.

Friend Root:—In your issue for Feb. 1, 1889, Mr. Eugene Davis, of Grand Rapids, in answer to your fourth question, as to best mode of heating lettuce-houses, says: "Our houses are heated with flues running under the middle bench, constructed so as

to give as even a temperature as possible." Can you inform me how his furnace and flue is constructed, in order that it may give this even temperature all over the whole length of the house, the houses being 16 feet wide and 50 feet long?

Aldersholt, Ont., Can. ROY M. BLESSINGER.

We at once forwarded the above inquiry to friend Davis, who replies below:

Mr. Root:—The furnace and flue that gives the most even temperature in my greenhouses is made as follows: A pit is dug, 4 ft. deep and 4 ft. wide and 9 feet long. The furnace is 5 ft. long, 22 inches wide and 30 inches high to the top of the arch, inside measure; the walls are 8 inches thick and 24 inches high, arched over with two tiers of brick. This leaves the top of the furnace about 15 inches below the surface; 18 inches of furnace should be built in the shed, for the chimney to rest on. The furnace-door is 16 by 20 inches, with draft in the door. The flues are four brick high, laid flat, and seven inches wide inside, with double tier of brick on top, 20 feet from the furnace. The brick is laid flat, 40 ft. from the furnace; then with 9-inch sewer-tile to chimney, or brick set edgewise, 3 brick high. There should be a gradual rise in the flue from the furnace to the chimney. When firing with *green wood*, never close the drafts, as the gas from the wood will kill the plants.

The chimney is on top of the furnace. The reason for it is this: As soon as a fire is started in the furnace, the air is heated in the chimney, and gives a direct draft. There are no grates in the furnace. In the first one I built I used them; but I saw the draft was good enough without. Any one handy with a trowel can build the flues, furnace, and plaster the cistern.

I am afraid these directions are not very plain; but my hand is more used to a shovel or hoe than to a pen.

EUGENE DAVIS.

Grand Rapids, Mich., Jan. 25, 1889.

The article from the *American Garden*, it will be noticed, has also considerable to say about the construction of greenhouses for lettuce. Friend Davis sends us, also, some diagrams, but I think they will not be needed with the full explanation which has just been given.

BOXES FOR PROTECTING MELONS FROM FROST, ETC.

I wish to use, the coming season, quite a number of the boxes over my melons in the early spring, such as you wrote about having made for the purpose of protecting squash and cucumbers from frost, etc. My object is to protect my melons from frost, so that I can force them very early. We had a killing frost last spring after melons had been up three weeks. This is what I wish to avoid in future. Please answer the following questions; and if you can not give answers from experience, then give me your opinion about the matter.

1. Would not a box smaller than the one 8 by 10 do as well (say one taking a glass 6 x 6 inches), where one or two plants are in a hill?

2. Would it be good economy to use half as many boxes as hills, transplanting to the other or open hills from the boxes? One plant is all that is desired in each hill after thinning out the last time. We plant cantaloupes 7 to 8 ft. apart, and watermelons 9 to 10 ft. each way.

ALBERT WITTENMYER.

Emison, Ind., Dec. 27, 1888.

Friend W., the only trouble with your *small* boxes would be that the frost would, as you will readily perceive, be more likely to freeze the ground solid clear through under them. This could be avoided, however, by banking up the earth on the outside, when the freezing is severe. With our tin transplanting-tubes, you can transplant melon-vines without the least risk, and rarely with any check in their growth. Another trouble with your small boxes would be that the vine would be very soon too large to be protected by it. This, however, does not as often happen with *boxes* as with the wire-cloth *baskets* for protecting them from the bugs. See what we said in regard to the matter on page 544, in GLEANINGS for 1888. My experience last season was not very favorable with the boxes for protecting plants from the frost. The *protection* is complete, and I saved my vines; but the discouraging feature about it was this: Seeds planted several weeks later, side by side with those that had been protected with so much pains, give melons and cucumbers almost as soon as the ones that had been started so early. I am inclined to think, however, that seasons as they usually come would give a different result. The same is true with tomatoes protected by the plant-boxes from the frost. We had so much wet weather, however, last season, that all kinds of vines kept growing, and did not commence to fruit as early as they do when we have more dry weather; that is, careful protection from frost resulted only in giving me *immense* plants; but they did not bear fruit any sooner than the *small* plants that had grown a much shorter time. We are going to get early tomatoes this year by planting them on *poor soil*; and I think if we could have kept off some of the extra amount of rain we had last year, from our melon-vines, we should have had *earlier melons*.

HENDERSON'S BUSH LIMA BEANS IN THEIR NATIVE STATE.

I see you have the bush lima bean illustrated, and I have read what you and others have said about it. We have had this bean with us two years, and perhaps longer. I planted a very few the past year, and gave them but little attention. Had I only known they would have been in such demand, I might have planted a quantity, and now been able to supply you and others.

J. W. HUDSON.

Maysville, S. C., Feb. 5, 1888.

Well done, friend H. I had a dim idea that perhaps GLEANINGS might be able to find out where these bush lima beans came from, for it makes its way into more nooks and corners than one might imagine, with a circulation of less than 9000. A great deal is due to the fact that it has a keen and enterprising set of readers, and a thing must be pretty difficult indeed if there is not one of them somewhere who gets hold of it. Now, don't you think that, if you "flax around lively," you can get hold of some of those beans somewhere in your vicinity? You need not tell anybody, but I will just whisper in your ear, they are worth about a cent apiece, even if they are small. And now, friend H., we want your private opinion publicly expressed, in regard to the

quality, compared with the big lima beans. And another thing, is it not a little tedious to gather and shell them, compared with shelling our great big ones—the “King of the Garden” limas, for instance? Who is there in your State or vicinity who can tell us more about the bush lima bean?

While I think of it, I want to complain a little of our good friend Peter Henderson. In all the glowing accounts we have had of these new lima beans, there is almost nothing said about their being so exceedingly small. When I opened my first package I was a good deal disgusted, and that is why I took particular pains to tell the readers of GLEANINGS what they might expect in the way of size before we sent out any of them. I know the temptation is strong to say all the good things we can about novelties, and to skip over the unpleasant part; but if a seedsman wants to keep the confidence of his patrons he will not only tell nothing but the truth, but he will tell the *whole* truth. Again, in Henderson's new catalogue quite a glowing account is given of a tomato called the Shah; but we learn that this is only a Mikado that is yellow instead of red. The first Mikados we ever got of Henderson gave us a few plants producing the yellow tomatoes; and for three years in succession we have noticed the same thing—occasionally a plant producing Mikados that were yellow; but as most of our patrons preferred the red tomato to the yellow one, we rejected them in saving tomatoes for seed, as being objectionable. Under the circumstances, is it right to bring this out as a variety? Nothing is said in the advertisement as to its being any more regular or any smoother than the Mikado. That being the case, I do not see how it can compare with the Golden Queen, which has for some years been before the people as a good-sized beautifully shaped yellow tomato.

Later.—In Landreth's new catalogue just received, we find a photograph of what he calls “Dwarf Carolina, or small lima beans.” The photograph shows a single stalk bearing an immense quantity of pods that look exactly like the pods represented by Henderson; and a package of the beans placed side by side of a package of Henderson's bush lima beans looks so exactly like them, that no one can tell the difference. Landreth charges 10 cents for a package of 25 beans, while Henderson charges 25 cents for the same. Henderson says his came from the South, and our correspondent from South Carolina says they have had them there for two years, and Landreth calls them Dwarf Carolina; so it seems pretty clear that it is one and the same thing. Landreth, however, does not herald them with any spread-eagle advertisement. Of course, we can tell *positively* that they are the same thing only after raising a crop of each. We can mail Landreth's at 10 cts. per packet, or Henderson's at 25 cts.

HOW TO RAISE SWEET-POTATO PLANTS.

I wish you would give some directions how to raise sweet-potato plants, as I am in the gardening business as well as the bee business.

Hastings, Neb., Feb. 1, 1889.

D. J. RADDICK.

Friend R., we have succeeded in getting a fine lot of sweet-potato-plants only once; then we cut the potatoes in two and turned them cut side down, and placed them in a warm spot in our greenhouse. They were very slow about starting, but we finally succeeded in getting some very nice plants. When they became crowded, and we didn't have customers, we pulled off the sprouts, or plants, and set them out exactly as we do celery and cabbage plants in our plant-garden, and they made strong thrifty plants about the time customers came for them. Such plants that have been transplanted so as to give them a good root, and make them strong and stocky, are certainly worth double the price of ordinary sweet-potato plants. If some of our readers are in the sweet-potato-plant business, and will give us a full account of how plants are raised for the garden, on a large scale, we will gladly pay them for the paper. Last season there was a scarcity, and we failed to get plants to fill orders, even though we telegraphed to many different points. Saving sweet potatoes so as to be in good trim by planting time, I believe is one of the most difficult points, especially here in the North; and if somebody who has nice potatoes suitable for plant-raising will advertise them in GLEANINGS, I think he would meet with abundant sales.

HOT-BEDS—HOW TO MAKE, ETC.

I should like some information on hot-beds, how and when to make them, and whether to use glass or oil cloth for frames. I want to sow my seeds about Feb. 15.

H. WHITE.

Spencer, O., Jan. 14, 1889.

Directions for making hot-beds have been given so frequently in most of our seed catalogues that it seems a good deal like repetition. The whole matter is very simple: My father-in-law used to make a very nice hot-bed on top of a smoking manure-heap. All he did was to dig down until he found the manure hot enough, then he put on three or four inches of good garden soil, set a box over it, and placed on top of the box a sash, banking the manure up around the box, clear up to the sash. He raised as fine plants as any I ever saw, by this means. Now, a hot-bed is nothing more than putting this manure into a square pit dug in the ground. They go into the ground to be more secure from frost, and to save the heat from the manure. The pit must be well drained, so that heavy rains will not drown every thing with ice water. Cloth is not as good as glass. In fact, it would not answer at all at a season of the year when we are liable to have heavy snowstorms. It is true, there is no danger of the plants being scorched by what sun gets through the cloth; and at a season when you simply wish to protect your plants from an occasional frost at night, the cloth answers every purpose. But the cheapest kind of common sheeting that we get at our dry-goods stores is every bit as good as the hot-bed cloth that has been advertised so much; in fact, we prefer the cheap cotton cloth from the stores. It is not so easily torn into shreds. Another trouble with cloth is,

the havoc that high winds make with the frames. We have chased after them so much, and wasted so much time in fastening them down, that we have about concluded the glass sash is cheaper in the end.

CORN SALAD.

You gave in GLEANINGS so excellent a plan for raising lettuce, would you not have the kindness to give advice for growing in cold-frames corn salad (fetticus, or lamb's lettuce), through GLEANINGS? It is much esteemed in the old country, but it needs there no planting, as it grows in all corn-fields spontaneously, and stands any weather and winter. It is there called "corn."

Sigel, Ill., Jan. 27, 1889.

DR. WM. HEER.

Friend A., we have some very fine corn salad now growing in one of our cold green-houses. We have raised it and sold it to some extent here in Medina. I believe, however, that but few people have learned to use it, except the Germans. We are very much obliged to you for the additional facts you give us, and we should be glad to be told more about it.

JAPANESE BUCKWHEAT; LIMA BEANS WITHOUT POLES, KAFFIR CORN FOR HOT-CAKES.

Here is my testimony regarding Japanese buckwheat: I sowed about a peck, and got 17 bushels. The seed came from Peter Henderson. We never saw a single bee at work on the blossoms, except the little wild "sweat" bees. The flour is equal to any buckwheat, and we sold it at 4 cts. per lb., but at the same price we sold 2 lbs. of the Kaffir-corn flour to one of buckwheat, and used the latter in our own family, most of the time. The garden talk found in your paper is very refreshing to me. The Henderson bush lima has caught the attention of gardeners; and if it did not look so small I would take more stock in it. Let me tell how I raise Jersey lima beans without poles. I run a fence, made of wires and lath, which can be had at 40 cts. per rod (3 strands and plastering lath), right where the row of limas is to stand. Plant the beans 6 inches apart, on the south side of the fence; and if they come up at all right, your row of limas will be the wonder of the neighborhood in September. I have picked a bushel of pods in two rods of fence.

Crete, Neb., Feb. 5, 1889.

M. S. BENEDICT.

The fact that you saw no bees on the blossoms, I do not think at all against the Japanese for honey, for many such reports have been made from common buckwheat. There are two causes that bring this about: First, the buckwheat may contain no honey, just as many other kinds of blossoms may contain no honey during certain seasons. Second, the bees may have found something else so much more to their liking that they would not notice the buckwheat. Sometimes, when this pasturage fails, they will start for the buckwheat with a sudden rush.—We have tasted the Kaffir-corn flour, for making cakes, in place of buckwheat, but we rather give the buckwheat the preference. The Kaffir corn, however, makes a very nice light cake.

WANTED, A SCHOOL FOR TEACHING GARDENING AND AGRICULTURE.

Dear Friend:—I received and read your book, How to Be Happy, with pleasure. It held my attention, though I know nothing about gardening. I

have taken a great notion for farm life, and I should like to know if you know of any schools teaching farm methods, dairying, fruit-tending, etc.—things you can not learn from books. I know there are State agricultural schools, and I have read of experimental and college farms, but nothing further.

MARY L. BONNER.

Davenport, Iowa, Jan. 17, 1889.

My good friend, our agricultural colleges, I think, will fill the bill exactly. The one at Lansing, Mich., has attained a world-wide celebrity; and the Experimental Station at Columbus, O., is beginning to become one of the institutions of which our State may well be proud. We should think that your own station in Iowa, where Prof. Chamberlain presides, who, by the way, has only recently left Ohio, would furnish all the advantages you wish.

FRIEND MARCH'S CABBAGE AND CAULIFLOWER SEED—REPORTS THEREFROM.

As far as my test is concerned, I can say I think they are extra. I put out nearly a hundred cauliflower-plants, and they all headed to a plant.

Wilsonville, Norfolk Co., Ont. ISAAC LUNDY.

From a five-cent packet of March's Select Very Early Jersey Wakefield cabbage seed bought of you last spring we got 431 nice strong plants; and after six kinds of bugs had satisfied their appetites, we got about 400 of the nicest cabbages I ever saw. We have just received a trial package of Ignoutum tomato seed, containing 26½ seeds, which we are going to plant in our little greenhouse, right off this minute.

B. L. SAGE.

New Haven, Conn., Jan. 24, 1889.

March's Jersey Wakefield cabbage seed, of which I bought of you one five-cent paper, gave me 340 strong, healthy plants. After I set them in the open ground the cut-worms proved to be very bad; and although I went over the patch every morning for a month, and caught from a dozen to 75 cut-worms a day, they destroyed half the plants; but all that were left made beautiful large and solid heads.

S. L. SHERMAN.

Oskaloosa, Ia., Jan. 9, 1889.

THE ONE-PIECE SECTIONS.

SUGGESTIONS IN REGARD TO THEIR BREAKING, ETC.

FRIEND ROOT:—My article in GLEANINGS, on "Folding Sections," brought me quite a number of letters and samples from different manufacturers. From these letters I deduct the following: 1. Sections made from old basswood are more liable to break than those made from young wood (second growth). 2. Kiln-drying destroys the elasticity of the wood, and makes it brittle, while air-drying does not have that effect.

3. The grooving-saws should not be too sharp-pointed on the edge, but rather a little rounding, so as to leave more wood in the bottom of the V-groove than is done by a sharp-pointed saw.

I am going to try sliced sections this year as their folding quality and rigidity after folding seems to be much superior, although in appearance they are not as "pretty" as sawed and sandpapered sections.

A PROPOSED SHIPPING-CASE.

I have in my mind's eye a (any) shipping-case for comb honey, with four little india-rubber balls, one under each corner. The balls should be solid, but with a hole through the center, just large enough to take a 2-inch wire nail. I suppose $\frac{3}{4}$ or 1 inch in diameter would be a good size for the balls. The wire nail should be "set in" so that the head would go to the center of the ball, and thus not interfere with its elasticity. I imagine that a case provided with 4 such balls under its corners would stand considerable bumping before the combs would break loose. What do you think of it? Would it be worth while—for you—to have them manufactured, and keep them for sale? Or would the balls interfere with the piling of cases on top of each other?

I once heard of a double packing-case with rubber balls between the cases, but I do not know if anybody ever used such. They would be too expensive, at any rate. WM. MUTH-RASMUSSEN.

Independence, Inyo Co., Cal., Jan. 7, 1889.

HONEY-EXHIBIT AT SPRING MILL.

AS ARRANGED BY J. W. NIMAN.

I HAVE taken the liberty to send you a photo of my apiarian exhibit at our county fair. As the name in the picture is something of a novelty, and has been admired by many thousands of people, I thought it might be of interest to the thousands of readers of GLEANINGS. I will here give you a brief description of the picture. At the extreme left is a bee-tent; next is a solar wax-extractor, and adjoining it is a queen-excluding honey-board. A bee-hive with a capacity for 100 one-pound sections is next in order. Thirteen stars of solar-extracted wax, representing the thirteen original States, stand out conspicuously in the background; beneath it is a queen observatory hive. Next is a pyramid of glass jars of different sizes; above it, a glass case five feet long; in it the name of your humble servant, made by the bees, as you see there in the picture, and over five feet in length.

J. W. NIMAN'S HONEY-EXHIBIT, SPRING MILL, OHIO.

I believe you are right, friend M., on all the three points you make. The rubber balls have been suggested, and used to some extent, not only for honey, but for shipping eggs for hatching. The trouble is with honey, that, where one has 100 cases or more, it would not be practicable to have them all set on these rubber balls. Where one has a good crop of honey, he had better load it on the cars himself if possible. Put a good layer of straw under the cases, and pile them up one on top of the other. Pack straw between the cases, at the side of the car; then if you can have some careful man to attend to unloading them, they can be shipped by freight without injury. If it be necessary to transfer from one road to another, then comes in a difficulty that can be obviated only, perhaps, by securing the whole car, if the crop warrants, thus having it shipped to its destination without transferring.

A Novice honey-extractor is at my right. In my hand is a Langstroth brood-frame of new comb partly capped over. At my back is a large case of honey and wax, and near them are bee-smokers. Back of the Clark smoker you can see a corner of an old box hive, with brimstone matches sticking in it, such as were used in old times to kill the bees to get their honey. On the ground in front is the apiary tool-box and swarm-arresters on the top of it.

J. W. NIMAN.

Spring Mill, Ohio, Oct. 10, 1888.

Friend N., your exhibit does you great credit. Your name, built out in honeycomb by the bees, must have proved quite a curiosity to the many visitors. Those little bits of comb built in the frames, showing how the bees start their work, not only exhibit the beauty of workmanship on the part of the bees, but it teaches people how comb is built, and the way in which bees go about it.

THE TARANTULA.

PROF. COOK ADMITS THAT SPIDERS MAY BITE.

MISS FLORENCE GREEN, Welde, Col., writes me as follows: "I send you a specimen of tarantula—not a very good one, but I hope you will tell us all about it in GLEANINGS, especially whether it is poisonous or not. The people here say that it is. We take great pleasure in reading the articles on insects, and we shall be much pleased if you will notice this."

THE TARANTULA.

This is one of the largest of American spiders, and is found from California to Missouri, and south into Texas. I send a good drawing of the specimen, so that all may see just what manner of creature it is. The scientific name is *Mygale Hentzi*. It is brown, and the drawing gives the correct size. As will be seen, it, like all spiders, differs from an insect in having only two parts to the body—the cephalo-thorax—head-thorax—which bears the mouth organs, eyes, and legs, and the abdomen. Thus the head and thorax, instead of being separate, as they are in insects, are united. They have no antennae and no compound eyes, but eight simple eyes arranged in two rows, as seen in the figure. There are eight legs instead of six, as in insects. Those front leg-like appendages, which bear the curious claw-like organ, are not feet, but the maxillary palpi, and so belong to the mouth organs.

These are ground-spiders, and live in holes dug in the earth. As to whether these are very poisonous, or dangerously poisonous, I am not able to say. All spiders have fang-like jaws and poison-glands, with attached poison-sacs, and so can extrude poison with their bites; but our smaller spiders can not bite very severely, and the poison is too scant to do harm. I never hesitate to pick up a spider, and never could get one to bite me so as to hurt, much less poison me. Of course, such a Jumbo of a spider as the tarantula would frighten most people, and we can readily see how terrible stories might arise, solely as the product of fear and imagination. If the tarantula were a Michigan spider I should try it, possibly with gloved hands at first, and I should not be surprised if I should find that I could handle this as safely as our common and smaller spiders. Where it costs nothing, it is always best to be cautious, so I advise Florence not to handle the tarantula till she proves that it can not or will not bite. A. J. COOK.

Agricultural College, Mich.

Friend C., you say these spiders live in holes dug in the earth. That may be true;

but you do not give our readers any conception of what beautiful silken-lined holes these are where the tarantulas live. More than that, they have one of the prettiest little doors, hinged as daintily as the lid to a jewel-casket, and the spider can shut the door in the face of his visitors if he choose. When on my brother's farm, one of the little boys brought me a nest to bring home; but in some way it was forgotten. The silken gallery is a sort of tube, with sufficient tenacity so it can be handled without danger of breakage.

AN A B C SCHOLAR 62 YEARS OLD.

HOW SHE FINALLY TRIUMPHED OVER DIFFICULTIES AND DISAPPOINTMENTS, AND CAME OUT VICTORIOUS.

MR. ROOT, DEAR FRIEND:—We consider you as such, and your name has become a household word. I have been wanting to write you, to ask that you would continue GLEANINGS, although we can not send you the money quite yet, owing to sickness in my family. My husband has been out of health the past year. He has bronchial asthma, and has not been able to do any thing for many months. I had a hard time the past fall, getting my bees ready for winter, not being strong myself. I had about 80 colonies. I sold 10, and doubled until I now have 56, all strong and in good condition for winter in Root chaff hives (all but seven). I commenced the season with 50 colonies. It has been a very poor season in this part of the country. I got only about one-fourth of a crop, and that not nearly as good as in a good season, both extracted and comb honey.

Mr. Root, I have wanted to tell you that I owe you all the credit for my success, as I did not know any thing, scarcely, about bees when I commenced. I saw a few old copies of GLEANINGS at a friend's house while on a visit, which gave me a great desire to possess a colony of bees. We were poor, and in debt. I thought I could learn to care for them, and may be it would be a help. My husband had no faith in the idea, so he put me off; but finally, after much persuasion he purchased a light colony in an old box hive in the early spring. They did not cost much, as they were not worth much, for they swarmed out and went off. I did not know that they could be fed. I felt so bad about losing my bees that my husband then bought a good colony. I was so delighted I gave them every attention I could. They swarmed five times. I put them in the American hive, as it was in use here at that time. I was much elated with my success, and I thought I was going to show my husband that I could take care of bees. But I did not dare to open the hives; so when winter came they all died, of course, as the old colony had swarmed itself to death. I was sorely tried, but I had no idea of giving up—I had grown wiser. I learned of the A B C book. I sent for that and GLEANINGS, and went to studying. The next spring, 1880, I had an opportunity of taking three colonies on shares. I had all the increase and one-fourth the honey. Since then I have wintered with very small loss—some winters none. I now have 50 chaff hives; and as I thought that number was about all I had strength to care for with all my domestic duties, I have tried hard to keep them down to about that, by selling some

and doubling up in the fall. I have succeeded nobly in doing so, although I have had between 70 and 80 colonies several times. My husband is no bee-man, and does not like the business. Since I commenced I have taken between 13,000 and 14,000 lbs. of honey, over one-half extracted. It sells here now for 15 cents, comb; 12½ extracted. Those troublesome debts are paid, and we have built us a good new house, which we much needed, and my husband gives the "blessed bees" credit for most of it. My husband and son did the work. I am almost 62 years old. If I were younger I would try to care for a larger apiary, as I do not lose my enthusiasm for the care of bees. My health is not good, but much better than it used to be before I worked in the apiary—so much that I feel as though I wanted to thank you for the biographical sketches you sent out with GLEANINGS. I am very much interested in them, but most of all in the one that appeared in GLEANINGS for Dec. 15. I can not tell you how much we prize GLEANINGS. I shall take that as long as I have any thing to pay for it, while I live.

I have wished many times I had Our Homes in binding of some kind. I mean ever since they were commenced. I have wondered if you had them.

I feel to praise God every day of my life for his goodness to me, and for all the way in which he has led me, and for the success he has given me in my labors; for it has come through much prayer and humble trust in him that I have been able to accomplish the desire of my heart in getting an apiary established on a small scale, and it is a cherished desire yet to be able to do a little more in helping on the blessed cause of Christ in the world. I am especially interested in the American Missionary Association. Oh how I do want to help more in that direction!

I am almost frightened when I see how much I am trespassing on your precious time, but I will promise not to do so again. You seem so much like an old friend that I almost forget myself.

We get our supplies at Jamestown, as the freight is much less. I was sorry to change.

Farmers' Valley, Pa., Jan. 8, 1889. MRS. E. C. OLDS.

By all means call me "dear friend," if you feel like it, *my* dear friend. I can not tell you how much it rejoices my heart to know that you have ultimately triumphed in conquering the intricate and perplexing minutiae of bee-keeping. I am really afraid that, had you asked my advice, about the time of your repeated disasters, I should have urged you to give up the business, and not try any more, a good deal as your husband probably did. In fact, I should have thought it almost impossible that one so well advanced in years as yourself could conquer the difficulties that every beginner must meet. However, you have given us a grand illustration of what may be done by one who has a steady enthusiasm for any such industry, right along, year after year. You loved bee culture, and did not tire of it, even though beset with repeated disasters, and therefore you conquered. The point you make, where the debts were paid and the new house built, is not only refreshing, but it is a good rebuke to those who say after they have got old, and let their bees go to ruin through *lack of attention*, that "bee-keeping does not pay." I think your hus-

band and son must be exceedingly good-natured to follow your directions when they have no particular interest in the matter. Another encouraging thing, like our good friend Mrs. Axtell you have found your health improved, as well as your pocket-book; and the improvement came, too, without the use of medicines of any kind. Now, any outdoor industry that gives us renewed health, without the aid of medicine of any sort whatever, is a grand gift from God, even if we do not make any money by it at all. When it pays the debts and builds houses besides, it amounts to one of the grandest gifts that ever came from the hand of the all-wise Creator. No doubt your heart was stirred within you by the accounts of Mrs. Axtell's great achievement with honey-bees, for we notice that you too are interested in missions. Never mind about trespassing on my time, dear friends, when you have such a story to tell as we have just had in the above. You see, I have taken the liberty of putting in even your last paragraph also; and I will tell you why I did it. I want to say to you, and to all others of the friends who read GLEANINGS, that, whenever you can buy your supplies nearer home, so as to be the means of saving you freight, or in any other way, remember it does me good to hear of it, even if your money does go into the pocket of some other brother; for I hope I have grace enough in my heart to wish to have you all do what benefits you most. If the money did come to us here at the Home of the Honey-bees, it wouldn't go to our good brother at Jamestown; and I am not sure but it affords me just as much pleasure to think *he* has been receiving good-sized orders, as if they came right here to us.

JOTTINGS FROM AMATEUR EXPERT.

ENGLISH BEE-KEEPERS; CARNIOLANS AND OTHER RACES OF BEES.

FRIEND ERNEST:—Your letter of Dec. 6th is before me. So you have foraged out my name and address from friend Blow, and now wish to make use of me. I thank you for offering to put me on your list of paid contributors; that, I must decline. I never write for "grit," but for amusement; moreover, my experience with editors is that they are an arbitrary class of men, so I keep free of them; and if they do not treat me as I think I ought to be treated, I am then in a position to throw up the pen and make my bow. I shall, however, be pleased to include GLEANINGS among my friends, as I always read it with very great pleasure, and it is my wife's first favorite among bee-papers.

You suggest a host of subjects for me to give my views about, naming Carniolan bees first. A very innocent remark of mine in the *B. B. J.* raised an awful "storm in a teapot" about these bees; and when it came to high words it was brought to an abrupt end by the veto of the editor. For myself, I was not sorry; but for people who are likely to be eased of their money in the future as in the past, I was very sorry. There are immense numbers of queens imported into England every year; and in my wanderings about I see great numbers of vari-

ous races. The trouble is, they are so very much mixed. It matters little what race you select, the trouble is to depend on getting them pure. Carniolans are the last foreign race in great demand—if I except the Minorcan—and most of us had hoped an effort would be made by the queen-breeders to keep them pure; but it soon became evident to those who watched what was going on, with a critical eye, that the same old game had reached Carniola also. I do not wish to blame any one man for doing this, but I at least did expect some to endeavor to keep their hands clean of such practices by keeping the yellow races out of the breeding-grounds, instead of introducing stocks in numbers to breed from.

I presume you are not aware that our law of libel in England makes it a crime to write and publish the truth, if it is calculated to injure a man in his business. Dishonesty with us, as everywhere else, does not succeed in the end; but we have not the ready means of showing up any "fishy" tricks that you have in America, as the parties would soon down upon us and get heavy damages; consequently one has to be very cautious, and so have editors.

Now as to the Carniolan bees. Why are they such favorites with us? To understand the reason, you must understand the class of people who compose a large number of our bee-keepers. First, we have the farm laborers, who keep bees in the old-fashioned straw-skep hive. They are very numerous in the parish (township, an area of 4000 acres) in which I reside; there are quite 40 who keep from two up to a dozen such stocks each. They never buy a fresh queen or swarm, but simply hive whatever increase comes naturally, and take the swarms in autumn, and return the bees (or in some cases even brimstone them), and appropriate what honey they may have stored, and allow the old stocks to stand over winter. The only good thing about this method is, they have always young queens at the head of their colonies.

Next we have a class of people socially a stage above these, who keep bees in bar-frame hives on modern methods and read the bee-papers, and keep the bees for what they can get out of them, as well as a relaxation from other labors. In my parish I have two other such besides myself, but the three of us would not keep 50 stocks between us, as we can not find time from other duties to attend to more, and I keep the greater portion of that number, the other two not being such lovers of it as myself.

We next have a class of people who keep bees for pleasure and profit, who enjoy moderate incomes, who keep a daughter of the laboring classes in their houses to do the work as a "slavey," and a lad out of doors to do the pleasure-ground and garden, clean boots, and do odd jobs generally. As a rule, these people live fully up to their incomes, are very poor and very proud. Indoors the wife would not wash a cup or light a fire on any account, while out of doors the master would not hoe a weed in his garden, or run a lawn-mower, for a fortune, if he thought his neighbors would see him. These people keep poultry for the sake of the eggs they lay, as well as to have something to interest themselves in outside of their duties. They also keep bees for a similar purpose. These are the people who use the bee dresses and gloves, etc., that form a part of bee-gear with us, and a real

good stinging from a fiery-tempered stock of hybrids would really be serious to such people, as well as inconvenient. I remember meeting one such one day who offered to sell his five colonies in bar-frame hives cheap, to be rid of them quickly. He was dreadfully disfigured; and on my inquiring why he wished to sell them he replied he could not bear to walk up the street, as every one he met "chaffed" him so—"What! been out late?"

Having said so much about our social habits, and bearing in mind the fact that Carniolans are remarkably docile bees, you will readily understand why they are such favorites with this class of people. As honey-gatherers they are as good as many sold here for Italians; they are also better comb-builders, as a rule, and they certainly are far more reliable in temper.

Our farmers, with extremely rare exceptions, do not keep bees, nor do their sons, daughters, or wives, seem to take to it. This with you is the contrary, I believe. Many of us are compelled to keep our bees very near our houses and pleasure-grounds, consequently their tempers often have to be a great consideration with us. The characteristics of Italians, Cyprians, and Syrians, that you inquire about, I must leave to a future letter. This is "Boxing-day" with us, and consequently a general holiday spent in feasting and idleness, so I am spending it by putting up arrears of correspondence. December has been a month of mild, damp, foggy weather. The air is saturated with moisture; and in places where there are no fires you can wipe the moisture off painted woodwork and such like articles, so you may imagine what the hives are like on their summer stands. AMATEUR EXPERT.

Friend E., although your letter was directed to Ernest, I want to express to you my thanks for your kind letter to our readers. I am very glad indeed that you have taken hold of this matter of false pride in regard to doing necessary household duties, and that you have handled it without gloves. Although there are not very many in our country, so far as my knowledge extends, who are ashamed to wash the dishes, light the fire, weed garden, or run a lawn-mower, there is a constant tendency here in that direction—that is, there are certain people who are ashamed to be found doing these things. I suppose that you are well aware that I have been strongly opposed to any such romantic notions. A great many times, when well-dressed runners inquire for the "boss" they are surprised, and may be now and then disgusted, to find him not as well dressed as some of his workmen, and perhaps engaged in "weeding garden," as you express it. There may be such a thing, however, as too great extremes in this matter. My wife thinks many times I ought to take more pains to be tidy and neat than I do. Doubtless she is right; but she prefers to do her own housework; and when you pay us a visit, which I hope you sooner or later may do, very likely she will light the fire and cook the breakfast for us with her own hands. I often tell my helpers that I shall never ask them to do any thing that I should be ashamed to do myself, and I think this contributes greatly to the pleasant relations that exist between myself and all who are working for me.

My wife remembers enough about her childhood home in "Merry England" to give us very graphic accounts of the people, climate, etc., even including the dampness of the winters, which you mention.

NOT QUANTITY BUT QUALITY.

MRS. HARRISON OFFERS SOME GOOD SUGGESTIONS TO PRODUCERS AND SELLERS OF HONEY.

MR. ROOT:—Mrs. Chaddock, in telling what I sold extracted honey for, has caused letters to pour in upon me at a fearful rate, offering honey in barrels by the score. I wish to say to one and all, that I'm not in the commission business. If I wanted honey, I would either advertise for it, or write to those who I knew had it to sell. The reason why I get 20 cents per pound for extracted honey is this: I'm an old resident of this city, having lived here nearly all my life, and am well known. Although there may be plenty of honey at the stores, persons will come long distances to get ours, fearing adulteration, saying, "It's bees' honey I want."

Those who report such large yields of extracted honey, and claim to produce it so cheaply, are an injury to the craft. I always feel as though my extracted honey cost me the most. This cheap way is certainly not the best way. The honey that I'm selling is pure basswood. The combs were entirely empty at the advent of the flow, and extracted before sealing. It was a ground-hog case. We were out of honey. The boy who was digging out a woodchuck on Sunday morning, who was reprimanded by a minister driving by said, "I must have him; we are out of meat, and the minister is coming to our house for dinner to-day."

The honey, as it came from the extractor, ran into jars or tin vessels, which had cheese-cloth tied over the top. When they were full, fresh cheese-cloth was tied on them and placed in the sun. The weather was very hot and dry. It is a mistake to let the honey run from the extractor into barrels, without straining. If this honey were to pass through the hands of that careful and painstaking woman Mrs. Muth, it would come upon the market all right, but it may not be so fortunate. She told me, when I was there, that when she "cooked" honey, as she expressed it, she skimmed it as long as any scum would rise; and on looking at the skimmings with a magnifying-glass, broken legs and wings of bees could be seen.

In lieu of trying to see how much extracted honey can be produced, it would be better to aim at excellence. I do not see how any one can tier up until the close of the season, and then extract and keep each kind separate. I lately received a letter from a person, complaining that he purchased two barrels of extracted honey from Illinois for clover, which was not the kind represented, and that he lost money on his purchase. Judging from the tone of his letter, it is evident that he thinks no pure clover honey is produced in this State.

Mr. Muth appears to have taught his patrons so that they keep the different honeys distinct and separate, so that the flavor of apple, clover, basswood, etc., is easily detected. Will Mr. Muth now take the floor, and give us directions upon this subject, and in what way the trade demands it put up?

By the way, Peoria has no need for the honey called "amber." I would not offer it to my customers as an article of food. I saw some of this honey in a store; and on questioning the proprietor he said, "I didn't buy that honey; a man left it here, and I wish he would take it away, for I would as soon have soap-grease in my store." This honey may suit manufacturers, especially cigar-makers, but it is not fit for table use. MRS. L. HARRISON.

Peoria, Ill., Jan. 21, 1889.

My friend, you make a good point where you suggest that, if we tier up the whole product of the season, on the Dadant plan, we have our spring, summer, and autumn honey all mixed up. May be some of the combs contain clover honey, others basswood, and still others goldenrod; and I am afraid that the operation of extracting would not be so managed as to keep the different grades separate. We should like to have our friends Dadant tell us their experience in the matter. Your strictures on amber honey, it seems to me, are a little too broad. Well-ripened goldenrod or Spanish-needle honey is very nice, and, to a good many, just as delicious as clover and basswood, although the amber color is rather against the sale of it. I am well aware, however, that there is a good deal of honey on the market that is not fit for any thing, unless it is for some kind of "manufacturing" purposes.

THE EXCHANGE DEPARTMENT, AND ITS USE AND ABUSE.

TRADING "SIGHT UNSEEN."

WE have reason to fear, from complaints which have come in recently, that some of the advertisers in our Exchange Department have taken advantage of the persons with whom they have made a trade, somewhat in the manner indicated in the heading. It used to be common among boys, but we hope it is not so now, to trade knives "sight unseen." That such a practice is a species of gambling, no one will deny. To those of our readers who may not be acquainted with the plan, we would say that two boys, having each a knife which they desire to trade, make the following agreement: One of the boys, A, says to his companion, B, "Let's trade knives sight unseen." Each clasps firmly his own knife in such a way as to conceal it entirely, and then says, "Whole sides, whole blades, or no trade." The knives are passed to each other simultaneously. It matters not whether the knife is new or old, or whether the blades are steel or iron, the trade is effected, and one of the boys is almost sure to get the better of the bargain, while his companion fares the worse, of course.

Now, we have reason to fear that some of our advertisers in the Exchange Department are making their trades somewhat in the same way. Very recently a transaction took place as follows:

Mr. A advertised in the Wants and Exchange Department something to this effect: "Wanted to exchange, a Mason &

Hamlin organ, worth \$135, for a two-horse-power engine." Among the numerous answers received to this advertisement was one received from B, who stated that he had a two-horse-power Shipman engine that had been "used only a year," and which was "in perfect running order." This he offered to give in even trade for the organ. B referred A to the postmaster, who answered that B was a wealthy farmer, and that his reputation for honesty and veracity was not to be questioned. Certainly it would seem that A had taken the necessary precautions. The exchange was made; but A was greatly disappointed to find that the engine was one of the oldest styles of Shipman, and he did not think it had been used within five years. The shipper was careless enough to ship it without even crating it. The result was, that some of the legs, pipes, and gauges were broken. Indeed, A says it is not worth the freight he paid on it. A wrote B at once, and the latter sent \$7.00 to make good the repairs, stating that he had never used the engine at all, but *supposed* it was all right. He also said that he was more than pleased with the organ. A immediately felt relieved, and sent to the manufacturers for the necessary repairs. The latter stated that the engine was so old in design that they had no duplicate parts or patterns, and could not make the parts except at a great expense. A then wrote B to this effect; but B made no response, and A has not been able to get any response since, although he has written him a number of times. The engine is utterly worthless to A; and as he is at a distance from any shop where the necessary repairs could be made, he does not feel warranted in running the risk on the *mere possibility* of doing it any good.

A, the receiver of the engine, was in close circumstances, and the loss was a severe one. He says he did not mind so much the loss of the organ as the fact that the engine will not help him to make a living. In consequence of this trade, to meet a payment on a certain debt, he was obliged to sacrifice his bees at \$2.40 per colony. Each colony was bright yellow Italians, in double-walled chaff hives, and should not have been sold for less than \$10.00 or \$12.00. A says he feels no ill will toward anybody. He only wishes us to make it a warning to others who enter into such transactions.

The Exchange Department is, beyond question, a great benefit to honest advertisers, but it can be the means of fraud on the part of one or both parties. We have given the above incident in order that our readers may exercise caution. Be sure to ascertain that the article for which you wish to make an exchange is as good as represented, or that it is of a recent pattern; how long it has been used, and how much it is worth from a dollars-and-cents point of view. Be sure to ascertain all the facts in regard to the responsibility of the party with whom you think of making the transaction; and if the amount involved is considerable, be especially cautious. If possible, employ some competent party in the place to look at the goods for you.

QUESTION 102 RECONSIDERED.

ARE THOSE COLONIES WHICH CONSUME THE MOST STORES IN WINTER THE BEST COLONIES FOR BUSINESS?

ANSWERS to Question 102 show so wide a difference of opinion, that one must surely be at a loss to decide how near any of the answers might possibly be correct. Likely no definite answer can be given to the question.

The time given from October to May, seven months, is too long a time to reckon on for the consumption of stores per colony for wintering. With us, brood-rearing is carried on very heavily during April, and commences early in March. For those two months, as much honey will be consumed as during the four previous months. This is for our locality. There are exceptionally few localities where bees are confined seven months to their winter quarters; and, with such, brood-rearing must necessarily be going on. I think 30 or 40 lbs. of stores for a colony, seven months, with brood-rearing going on, is not too much. Messrs. Dadant & Son have not overestimated the amount for that period of time. Dr. A. B. Mason gives 6 to 11 pounds. He may be correct also; likely not, from October to May.

We have made cellar wintering our way for safe wintering for the past five years; and, to tell to a certainty what we gained besides the security of safe wintering, we weighed a sufficient number of colonies to get an average of what our colonies consumed while in confinement from the time they are put into the cellar and taken out, which is generally from Nov. 1st to April 1st—five months. We find for the past three winters that our colonies consumed from 3 to 12 pounds. The most of the number weighed consumed 8 and 9 pounds. We think those numbers would be very near an average for ours, only one colony consumed less than six pounds, and that one consumed 3 pounds, and was a strong colony. Said colony did as well as any that season (the summer of 1886).

In answer to the question, "Which is the more profitable, a colony which consumes more or less stores?" we could hardly say the one that consumed the most, if Question 102 means strictly the amount consumed in wintering. If 20 or 25 pounds of stores are used in wintering, and none of that amount is used for brood-rearing, that colony is no better off than if it had consumed 10 pounds if wintered in a suitable place. Colonies that we have wintered with suitable packing on their summer stands, consumed from 20 to 30 pounds in five months. Knowing the difference in stores used for outdoor and cellar wintering, we built another cellar two years ago at our out-apiary, and have now 100 colonies in it doing nicely. We have also 101 colonies at our home apiary in a cellar in which we could easily winter 400 colonies. The temperature at which our cellars are kept ranges from 40 to 45°. We haven't a single colony out of doors; and with the assurance of saving an average of 10 pounds of honey per colony, we think it pays to winter in the cellar.

J. NEBEL & SON.

High Hill, Mo., Jan. 21, 1889.

I know, friends, that certain colonies sometimes consume great quantities of stores, without being any better for it. But what I had in mind was where a colony consumes its stores in healthy brood-rearing, so as to require the larger amounts to

carry them clear through until the month of May.—The point you make in regard to the saving of stores by wintering in the cellar, even so far south as Missouri, is something worthy of consideration.

RAMBLE NO. 10.

THE USE OF A BLACKBOARD TO BEE-KEEPERS, ETC.

BEFORE starting upon this ramble I wish to show the fraternity a very handy article to have in the apiary. It is no more and no less than a common blackboard. Now, some one will probably say, "For conscience' sake, are there not enough traps now in the apiary, without lugging in a blackboard?"

Well, friends, let us explain. The hives in every well-regulated apiary are numbered, and have slates or something upon which to keep a record. If you put a record on the slate, of something to be attended to in a few hours or a few days, or even weeks, there isn't a bee-keeper having a large apiary but will often forget the record. The blackboard, if put up in a dry, conspicuous place, any fact placed upon it will be staring at you every time it is passed, and is thus a constant reminder of something to be attended to. Have you discovered a hive that needs more surplus room? If you are not ready just now to accommodate them, chalk it down on the board. Is there a queen to supersede, or have you caged a score of queens that need releasing at a certain time, chalk it down. We can not enumerate half of the items that will be put

facts, and there are many bee-keepers who will be interested in one very curious fact.

The pigeon is the only bird that feeds its young with digested food. We are all familiar with the method the old pigeon uses to accomplish this, with old and young bills interlocked; and some authorities go so far as to say that this food has had two digestions—first by the male bird, then by the female. Be this as it may, the effect is remarkable; for the growth of the young pigeon is unequaled by any other family of birds. When hatched, the little pigeon weighs about half an ounce; in six days it gains to four and one-half ounces; on the ninth day, over eight ounces; and at the age of one month, over twelve ounces, or somewhat heavier than one of its parents.

While other young birds have to digest the worm, grub, or grain, the pigeon simply grows with no exertion whatever; the prepared food is simply absorbed.

The bee-keeper will readily see that there is much similarity in the life of the young pigeon and young bee in the previous preparation of the food; and if the young pigeon has the benefit of two digestions, is there any reason to think that the royal jelly in the queen-cell is not the result of many digestions?

PORCUPINES.

Our next call was upon an accomplished and successful poultry-breeder, Miss Kincaid. We wished to investigate a new breed of poultry which was exciting the public for miles around, and about which people were indulging in much loose and inflated talk. These fowls were popularly called Porcupines.

The Rambler, upon presenting himself, was somewhat frustrated, as a modest man always is before beauty and talent; but after a few preliminary remarks about the weather and the crops, I felt entirely at ease, feeling that Miss K. was much like our own folks. In fact, she reminded me of my cousin Flora Jerusha. After stating that my business was mostly through curiosity to see her wonderful fowls, we adjourned to the neatly arranged poultry-yard; and the sight there presented fully aroused the curiosity of the Rambler. It is said that beauty is only skin deep on human bipeds; and so I suppose it is only feather deep on fowls; if so, then the beauty of the Porcupine fowls lies at the roots of the feathers. Beauty is not distinguishable on the surface. The prominent noticeable feature in the Porcupines is the position of the feathers, which are somewhat pointed, and stick out at all angles, but mostly toward the head. They are not quite so happy-appearing as other fowls, and the roosters have a dilapidated, disconsolate look. I was assured, however, that the hens were great layers, good sitters, and excellent mothers. Being of only medium size, they were not so well adapted to table use, but the meat was very tender, even to old age. While I was thus being favorably impressed with the fowls, a talkative neighbor came along and gave some more interesting points.

"Why," said he, "stranger, you can put them right down in a posy-bed, and they won't scratch. You see, if they kick back too far those sharp feathers prick their shins, and they stop instantan-

"Then, stranger, there is another point that shows their intellectual superiority. When they come to a hole in a fence, if their feathers prevent an easy passage head first, they jest turn around

THE RAMBLER'S BLACKBOARD.

upon the board during the season; but, believe the Rambler when he tells you it will save steps and worry, and enable you to do things at just the proper time. Try a blackboard. I give it to the fraternity. The record on our board now reads as seen in this sketch.

PIGEONS.

We ramble this time among the bird-fanciers. In our boyhood days, pigeons or doves were common among our best-loved pets; but if any one had asked us, a few months ago, if there was anything in the life of a pigeon that reminded us of bees, we would have given our head an incredulous shake. A short visit to a fancier gave us many interesting

and back through, tail first. It's very comical, stranger, very comical."

"VERY COMICAL, STRANGER, VERY COMICAL."

Miss K. frowned very heavily upon the fellow, and assured me that it was only a small specimen of the inflated talk that was going around the community about her poultry. After an interesting study of fowls of various strains, I ended my very pleasant call and went my way, thinking of the solid facts to my profit, and laughing at the chaff.

That the young women of our land have so many avenues through which to show their enterprise and success, rejoices the heart of the

RAMBLER.

Friend R., I do think your blackboard might be an excellent thing; in fact, a blackboard is now in use among our berry-pickers. As fast as the children bring in boxes of berries, the boss writes their name on the blackboard, and gives them credit. They watch him while he does it; and if they assent to his blackboard record, no further discussion is allowed in regard to it. In this way each one can see how he is getting along, compared to his companions; and when he has finished for the day there can be no discussion, because the whole story is not only in plain black and white, but in big figures and letters at that. It may not be necessary to inform our readers that the Rambler is supposed to have put his bees away for winter, on the plan recommended by friend "A. B. Ma—." With wonderful wisdom and forethought he is just in the act of noting that all that die are to be charged to the account of "A. B. Ma—."—I have often thought of this matter of the way pigeons feed their young on digested food. I did not know, however, of the wonderful rapidity of their growth. Now, I want you to tell us just one thing more: Of what age are the young pigeons when they sell them for table use? In many places they are considered a rarity, and bring large prices.—Why, old friend, you enjoyed yourself almost as much during your rambles as I did in California. Next time I take a trip I hereby give you notice to come along with me. Both of us together would probably find most things of interest; and you could hunt up the funny items.—Are we to understand that it is yourself with your hands on your knees in the picture, or is it the neighbor who said the new breed would not scratch, and that they crawled through fences back end first?

SIZE OF SECTIONS.

DR. MILLER DISCUSSES THE MATTER OF HAVING SECTIONS OF HONEY WEIGH EXACTLY ONE POUND.

THE foot-notes to friend Kelley's remarks on page 57 leave but little to be said; but as the matter is important, I may add a word. It is unfortunate, if not wrong, to call a thing more than it is, and I am in full accord with the idea that we should give good weight, and approve the motive that impels friend Kelley; but there are difficulties in the way that make it, I think, not desirable that we should try to get up a section that will sell uniformly as a pound. Most bee-keepers sell their honey in no smaller quantities than by the case; and I never knew a case of honey to be sold otherwise than by actual weight; so when you sell your grocer a case or a ton of honey, so far as you are concerned it doesn't matter a particle whether the sections average 15 or 17 ounces, nor whether the sections are uniform in weight, or vary a quarter of a pound. If there are 24 sections in the case weighing 22 lbs., you get pay for just the 22 lbs. you sold, and so far the transaction is a righteous one. Let us follow it up. If the grocer, as he should do, weighs every section he sells, and sells it for just what it weighs, then every thing is right to the end, no matter how light or heavy the sections may be.

Before going any further I will answer friend Kelley's request, and give some weights of the so-called 1-lb. sections; and in order to have a general result I will refer to my book and give the average weight in ounces of a section in a lot of sections in each one of five years, together with the average weight of a section in the lightest and heaviest case in each one of the lots.

	Average.	Lightest.	Heaviest.
1879	15.60	14.80	16.93
1881	16.34	15.00	18.00
1882	16.10	14.30	17.16
1883	14.62	13.66	15.30
1884	15.50	13.66	16.66

Notice, the number of ounces in the lightest and heaviest columns doesn't mean the lightest and heaviest section in the lot, but the average weight of a section in the lightest and heaviest case in the lot. Thus, the average weight of a section in the lightest case in 1884 was 13.66 ounces; and as these sections varied, the probability is that the lightest section in that case was not more than 13 oz. The heaviest case in the whole (in 1881) contained sections averaging 18 oz. each; and I have no idea that the heaviest section in that case weighed less than 18½ oz.

The first conclusion I reach from this table is one that surprises me. It is, that, with me, the 1-lb. section probably averages not less than 16 oz., taking it for a series of years. You will notice that there were three years when the average was below 16 oz., and only two years when the average was above. But the two crops of those two years were nearly as heavy as the three crops of the three other years; and I suspect that, if all the pound sections I ever raised were averaged, they would come as near 16 oz. as any size of section that could be made. Of course, I can't be sure of this, and I don't think it matters.

Let us now follow those two cases in which the sections averaged respectively 18 and 13.66 oz. I sold them by weight, so my conscience is all clear.

After leaving my hands I presume they went into the hands of two different grocers. If sold by weight there would be no trouble; but if sold by the section, the one grocer couldn't afford to sell at the same price per section as the other, so there would be trouble. But suppose both cases fell into the hands of the same man, and he sold them at the same price per section throughout, there would be injustice to the customer who paid the same price for 13.66 oz. that another did for 18. Every now and then some one starts up this subject, and I should like to impress the point that there is no such thing as a section that shall always weigh the same; and even if you succeed in finding one that will average 16 ounces this year it will probably differ next year. Now, friend Kelley, the thing to do is to quit striving for the unattainable, but use your influence to oppose selling sections by the piece, and insist on their being sold by weight. The former simply gives a chance for trickery, for I know there are some who sell by the piece; and it is a fact that the commission men will tell you that they can sell light sections better than heavy ones. Let us insist on weight in selling sections, always.

I am surprised to find that, notwithstanding the poor yield of 1888, 888 first-class sections averaged 15.7 ounces each. C. C. MILLER.

Marengo, Ill., Jan. 24, 1889.

There is another point, doctor: We should all of us beware about being in haste to accuse anybody of deliberate cheating. I am sure there are not many bee-keepers who have a desire to deceive their customers, especially on a matter where the use of a pair of scales would so quickly detect the fraud. Think what mischief has been done by being in haste to think evil in this matter of false statements in regard to the adulteration of honey!

NINE TONS OF HONEY.

BEES AND BERRIES.

I HAVE been much interested with your Notes of Travel. I was in California two years ago, and bought 10 acres of land 35 miles north of San Diego, in the Escondido Valley, and thought I should move out there as soon as I could get ready, but I am not as yet convinced that it is a better honey or strawberry country than this, or yet healthier. I put in cellar 180 colonies of bees this fall. The last two years I have extracted over 9 tons of honey. It has netted me about 6½ cents per pound. With the help of one hired man I work my 80-acre farm. I have help at my out-apiaries. I give them an interest in the bees.

Last summer I raised 41 bushels of strawberries on four rods less than one-fourth acre. I was busy with my bees when strawberries were ripe, so I told my wife that, if she would see to the picking of them, she might have all she could make and I would see that they were taken to town. She quietly pocketed 50 odd dollars, besides ten dollars in trade. I think it was the best investment I ever made, as it was so handy to borrow a dollar or two now and then, to be paid back when the honey was sold, and then it seemed to go so far. If I had had had it, it would have been gone in no time. I think if I live and have luck I shall do so again. I should like to raise comb honey, if it were not so much work, and not so much danger in shipping. I have

a plan on which I should like your opinion. It is simply a box, made of very light material, to hold 7 one-pound sections, with light tins nailed on the bottom, and a bee-space above, so they can be tiered up. Four of those would go on a hive, to be taken off completed, a box at a time, and shipped about 8 in a crate. The boxes could be covered with light berry-box material when packed in the crates, and nailed slightly with small wire nails. They could be pried apart a little, to lift the sections out.

Viroqua, Wis., Jan. 12, 1889.

WM. COX.

In regard to moving I think you are right; so long as you and your wife are doing as well as you have been doing where you are, I think I would let that California arrangement lie still, for you will have many drawbacks and inconveniences before you can get things into shape there.—There are several modifications of the plan you mention, for a honey-box holding 7 sections; but I believe they have not found very much favor. The arrangement is more expensive than the T supers, and does not seem to ship as safely as the ordinary cases made expressly for shipping the honey. If you ship the boxes, containing the 7 sections, with them, you have an additional amount of material to ship and to be returned if not lost.

THE PRESS STRAINER, FOR BEE-KEEPERS.

SOMETHING FOR EXPRESSING WAX AND SMALL QUANTITIES OF COMB.

I PRESUME that most of the friends have seen different forms of these fruit and vegetable press strainers advertised. In fact, a friend sent us a cut of one clear from Australia, saying that we certainly ought to keep that on our counters. The cut below gives a pretty good idea of the machine.

FRUIT AND VEGETABLE PRESS STRAINER.

It is simply a metal pocket, made of galvanized iron and heavily tinned plate. The sides of the pocket are made of perforated tin. To use it, raise the handle, fill the pocket with grapes, currants, strawberries, or any other sort of fruit. Now bring the handle down, and every particle of juice is squeezed out so as to leave but comparatively dry pomace. It can be used for mashing potatoes, prepared sweet potatoes, or pumpkins for pies, mashing turnips, making catsup, making beef tea or broth, rendering lard, and last, but not least, rendering wax on a small scale. Throw your pieces of comb into boiling water until they be-

come soft, then put them into the strainer and squeeze out the wax, or put your bits of comb into a coarse bag, not too large; and when it is boiling, drop it into the machine and push down the lever. The latter arrangement is also used for getting the juice from berries, and where there are many small seeds. If your paste or paint is lumpy, put it through the press and all your troubles in that direction are ended. In the same manner it can be used for almost a hundred different purposes. The regular price is 50 cents; but by buying them in quantities we can furnish them for 25 cents. If wanted by mail, you will have to send 20 cents extra.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

FASTENING FOUNDATION INTO BROOD-FRAMES BY NAILING IN A STRIP.

YOU will please find inclosed a small section of an improved top-bar for honey-frame. As it is very simple, it needs but little explanation. The object of this device is to facilitate the work of fastening the foundation in frames, one of the triangular strips being nailed fast, as you see. The comb being clamped between the two strips, the latter can either be fastened by nailing, or a little wax be used to make it stick. As you are a practical man, you will readily see the merits of this little invention (if it has any), without further explanation. I have shown the device to several bee-men, and they all seemed to think it a good thing. I do not send this as a "patent" to sell to you, but simply to give to you. If you can make use of it it will be a gratification to me if you do so. I am not a bee-man; in fact, I don't think I ever shall be. Being a mechanic, I am sometimes called upon to make a few hives, etc., for bee-men. My wife is a little struck on bees ever since she has been reading GLEANINGS.

Bellville, Tex., Jan. 15, 1889.

J. J. STOPPLE.

Your device, friend S., is very old. It was illustrated in one of the back numbers of our journal, GLEANINGS IN BEE CULTURE. It never came into practical use, for the reason that such a fastening costs too much, and was little if any better than the comb-guide method of attachment—that is, pressing a sheet of wax on to the guide.

A FOUL-BROOD INSPECTOR FOR CALIFORNIA.

The Board of Supervisors have seen fit to appoint me as foul-brood inspector for Ventura Co. The county pays me for my time. I think that, if the bee-keepers do not avail themselves of this opportunity of getting rid of foul brood it will not be the fault of the new Board of Supervisors.

HONEST BEES AND HONEST NEIGHBORS.

I remember that, when you were here, you expressed some surprise at my leaving 15 tons of honey in a frail shanty at the apiary, 10 miles from Newhall. I just came from the apiary, and I found every thing just as I left it in August. People don't steal bees or honey in California. I have been a bee-keeper for 16 years, but I never had my bees winter as well as they have this winter. I have 800 hives, and my loss this winter is only three

hives to the 100. About the same number are out of honey. The rest are full of honey, and I shall have to extract several tons before the new honey comes in. My bees are honest, as well as the people in California. I had six hives that were upset. They had been lying on their sides for months, for aught I know, with the supers full of honey, but were not robbed. This is a case of honesty or home protection (or what is it?). L. E. MERCER.

San Buena Ventura, Cal.

Friend M., it rejoices our hearts to hear of instances like those you mention above. The indications all seem to point now to the fact that we may not only very soon dispense with the fences around our dooryards, but that we may save money which we have heretofore invested in padlocks and expensive burglar-proof buildings to protect our property. You certainly have a very nice set of people around Ventura. Why, even here in Ohio, where we have schools and churches in every little town, and at a good many of the road-crossings, crops of wool and grain are quite frequently taken out of barns; at least, such cases did happen a few years ago. I wonder if it is not true, that the whole world is climbing up a little higher in this matter. I am very glad that you have received the appointment of inspector of foul brood, and I hope you will do your duty faithfully.

CALIFORNIA HONEY; ITS GRADES AND QUALITIES.

I have been very anxious to see something from you about the honey produced in California, as you no doubt had a good opportunity while there of learning from what source, and in what part of the State, the best honey is secured. I have bought and sold a good many tons of California honey this season. Some of the honey is, to my taste, the finest in color and flavor that is produced in the world, and, again, much of it is the most disagreeably flavored honey I have ever tasted, if I may except some of the dark grades of Southern honey. The white, or water-colored California honey (when entirely free from that disagreeable flavor found in almost all of the amber honey) is superior to our best clover honey. Every time I have sold this ill-flavored amber California honey it has greatly displeased customers. I wish I could find the producer or dealer in whom I could rely to give me always the best grade. It would be interesting to your readers to have what you must have learned about the different grades of honey produced in California.

J. A. BUCHANAN.

Holiday's Cove, W. Va., Jan. 7, 1889.

Friend B., the amber-colored honey of California comes mostly from the valleys and low lands. The beautiful water-white sage is found only among the mountains, and away up in the canyons, where the bears, and lack of civilization and neighbors, and many other things, make it unpleasant to camp out; and most of the bee-men, as I have told you, are getting back away from the fruit-lands, into the mountains, where the sages flourish. Other people besides ourselves have discovered the good qualities of the water-white mountain-sage honey of California; and whoever gets it in the future will have to pay a good price

for it. I am glad of it too, because it tends greatly to encourage pushing bee culture out among the mountain-wastes.

FEEDING BEES IN THE CELLAR.

I should like to ask you if it would be safe to feed in the cellar for the purpose of building up stocks, say $\frac{1}{2}$ pint every day. I mean, I should like to have them strong for the fruit-blossoms (about the 25th of April), which are very considerable here—apricot, cherry, plum, apple, peach, pear, raspberry, and others. If you can answer immediately, it will oblige me very much. M. D. OWEN.

Douglas, Mich., Feb. 5, 1889.

Friend O., feeding *has* been done in the cellar successfully, but a good many others have had trouble. If you want to feed liquid food, you will have to fasten the bees in the hive by means of wire cloth, or the excitement of feeding will make them come out—at least, it is pretty apt to do so; and if confined and fed a liquid food, they are quite likely to get the dysentery. By far the better way would be to give them candy; but I would by no means think of feeding them any thing unless it were to prevent them from starving. If you commence feeding them liquid food for stimulating, when they are gathering their first pollen, I think it will be soon enough; and even then I believe that many think that better results are obtained by giving them combs of sealed honey. Some recommend uncapping the honey to stimulate them to raising brood more rapidly; but urging brood ahead of the season is *likely* to do harm, no matter how you manage it.

WHY BEES BUILD COMB BETTER AT ONE TIME THAN AT ANOTHER.

C. C. Miller's problem as to whether bees build heavier comb at one time than at another, p. 20, is very satisfactorily solved. But in a super of mine containing 28 1-lb. sections I observed something so different from any thing that I had ever seen before, that I called the attention of Mr. C. C. Eddy, a bee-man, to know if he had ever witnessed any thing like it; and his reply was that he never had. If C. C. Miller's theory is universally true, then I should be pleased to know why all of the middle sections in a super I had, contained nice beautiful thinly drawn comb, while all the outside sections contained some of the heaviest and most ill-shaped comb I ever saw, resembling mud wasp cells. I use the house apiary. The supers are set on top of the hives, and with an oil-cloth cover on top, and nothing around the super. The doors were kept open, and there was plenty of ventilation, until the honey-flow closed. The colony to which the super in question belonged produced over 100 lbs. of comb honey the past season. J. A. GOLDEN.

Reinersville, O., Jan. 25, 1889.

As you state it, friend G., we feel pretty sure that you gave your bees *too* much ventilation—that is, their surplus receptacle was too cold for them to build uniform comb throughout the super. You say the middle sections contained thinly drawn comb, while the outside ones contained heavy comb. Of course, the middle sections were directly over the brood-nest, where there was the greatest warmth. The outside sections were subjected to the cool-

er air from without. You know that comb-building, in order to progress properly, should be in a close compartment, with a moderately high degree of temperature. The comb in the warmest parts of the super would work the most easily. That near the outside would work harder, and the bees would no doubt take less pains to thin it down.

A MINNESOTA BEE-CONVENTION.

A convention was organized here on the 17th of this month, for the purpose of getting together all the bee-keepers in the State, and many from Western Wisconsin and Northern Iowa, as quite a portion of those two States is near Minneapolis. The first meeting will be held at the Experimental Farm, with the Horticultural Society that meets in June next. All bee-keepers, and those interested in raising small fruits as well as bees, are earnestly requested to meet there. I assure you that you will have a good time. Due notice will be given through the bee-journals and the press. All correspondence will be cheerfully answered by the secretary,—

WM. URIE.

Minneapolis, Minn., Jan. 22, 1889.

THE MANZANITA OF CALIFORNIA, ETC.

I send you a twig of manzanita bloom. The bees have been working on it since the first of this month. We have had but little rain since you left. I will say nothing about the honey crop until I get it in tanks. I was sorry you could not stay with me a few days, but I suppose the old gent and I would have smoked you off the ranch. I hope to see some of your folks out next winter, to come and stay awhile.

G. W. LECHLER.

Newhall, Cal.

Friend L., we found a few bushes of the manzanita in bloom the day we left your beautiful ranch. Please give my respects to Mr. Friendship, the "old gent," as you call him, and tell him for me that, when you two old cronies have your big smoke, be sure that none of the boys are around, for it might teach them bad habits. I hope that huge tank will get filled a good many times during the coming season.

ROARING IN WINTER QUARTERS.

I wish to say a word in regard to Question 95, Dec. 15, page 969, about bees roaring in the cellar. A year ago last November, while passing through my bee-yard I heard a colony roaring so I could hear them plainly several paces off, and found them crawling on the bottom-board and front of the hive, outside; and upon opening the hive, every bee, so far as I could see, was on the move, as if looking for something, but none took wing. The temperature was several degrees below freezing, and the roaring lasted several hours. The next January I heard another roaring in the same way, in the cellar. I marked both hives, and in the spring found both queenless.

M. B. HAMMOND.

Ellenburgh Center, N. Y., Jan. 11, 1889.

Your point is, friend H., that this roaring is in consequence of queenlessness, or rather, perhaps, that the colony has just discovered that it is queenless. If giving them a queen results in quieting them, which it would, very likely, it would strengthen your position. I have seen colonies out of

doors in the summer time, running all over the hives, each bee making a mournful noise with its wings, and this happened not long after I had removed the queen; therefore I took it for granted that it was a lamentation over the loss of a queen. At such times the colony is pretty certain to accept any sort of queen you have on hand to give them; and some authors have recommended removing the queen and waiting until the bees begin to mourn or "roar," as you term it. The trouble is, however, the greater part of the time they start queen-cells without any roaring at all; at least, we do not discover any.

WHITE CLOVER; WHAT IS AND WHAT IS NOT FAVORABLE TO ITS GROWTH?

I should like to read a thorough essay on the subject of white clover, particularly as to what conditions are most favorable to its growth, and what kills it off so thoroughly some seasons. Five years ago, when I came to this State, it was abundant everywhere, and two fine crops of honey followed the succeeding years. Then the dry August and fall of 1886, followed by a severe winter, destroyed it almost completely. Was it the drouth or the winter, or both, that killed it? Will freezing and thawing kill it as it does wheat and red clover?

Chillicothe, Mo., Jan. 9, 1889.

B. A. RAPP.

I think that freezing and thawing does kill white clover, but I am not prepared to answer further as to why it is plentiful during some seasons and not at others.

THE EFFECTS OF THE RECENT CYCLONE IN A PENNSYLVANIA APIARY.

Wednesday afternoon, Jan. 9, we had a regular old-fashioned western cyclone. It went right through our bee-yard; and when I went out I would almost have given away bees, hives, and all. The wind upset 15 or 20 hives, dumped the bees on the ground, then carried the empty hives away. Some of the hives were blown 200 ft. I was out as soon as the worst was over, and picked up all I could. From some of the hives we lost over one-half the bees, as it was blowing and hailing. Next morning I went out and picked up bees by the handful, brought them in, and revived them. Within a square of our place, four houses were leveled to the ground, besides a part of a large factory just finished (Demorest sewing-machine factory), but happily no one was hurt. I hope the next cyclone will take another direction.

FRANK W. LIGHTON.

Newberry, Pa., Jan. 17, 1889.

Friend L., we are very sorry to hear of your losses during the storm of Jan. 9; but it verifies what I said about the warning the barometers gave us on that morning. Most of you, probably, have heard about the destruction of the bridge just below Niagara Falls, at the same time. I knew nothing about that when I wrote that editorial on page 69. Not only serious losses of property, but a great loss of life, resulted from that cyclone which our barometers foretold.

A NOVEL METHOD OF FINDING BEE-TREES, AND A GOOD ONE TOO.

Although out of season, I thought I would send you a plan for bee-hunting. Get on the north side of where the bees are likely to be, and in an open space if you can. Get a good line. If the sun has

passed that line for the day, leave it and go the next day; and when the sun gets on the line, with your hatchet in your hand start for the sun, lopping bushes or marking trees as you pass, and mark the line to the extent of where you think they go. Then retrace your line and find your bees. I have never failed to find them over four rods from my line, and that was where they were behind a high hill, and would pass a low point of the hill, and then take nearly a right angle to get to their home. If you get two or three lines, as I have sometimes, take the early one as the sun comes to it, and then the next, and so on. J. ANDREWS.

Pattens Mills, N. Y., Jan. 9, 1889.

THE BEST TREES, BOTH FOR TIMBER AND HONEY.

Do bees get honey from the following: White-ash and elm blossoms? soft maple? walnut-blossoms? honey-locust? box-elder? larch-blossoms? What trees are best to plant for the combined purposes of timber and honey? There are no natural forests here, but we plant our groves.

Sharon, Kas., Jan. 23, 1889.

J. L. PELTON.

I believe that bees occasionally work on all the trees you have mentioned, and, for that matter, there is scarcely a tree or plant known, that produces blossoms, that is not visited by the bees, say during an occasional season. Probably the best honey-plant in the world, all things considered, is basswood, and basswood timber is now bringing a very fair price, for a variety of purposes. I think I would put whitewood (or tulip) next. Perhaps others can help fill out the list.

DOES SHADING HIVES TEND TO DISCOURAGE SWARMING?

What effect would a shade over hives have on swarming—shade high enough for an operative to be able to walk under, the same as Casanova's, of Cuba, shade to be put up about June 1st, so bees would have the advantage of the sun nearly up to swarming time? What has been the average crop of honey for the last 10 years in the different localities of your answering correspondents? State comb and extracted. I. LANGSTROTH.

Seaforth, Ont., Can., Jan. 23, 1889.

It has been several times suggested that bees often swarm because their hives stand directly in the sun, and get too hot, especially where the hives are dark-colored. I am inclined to think that the color of the hive and its full exposure to the sun might have some effect in hastening the issuing of swarms.—The average crop of honey secured by the leading bee-keepers in the United States, according to reports in our Question-Box for Sept. 1, 1887, was 50 lbs. per colony for comb, and from 75 to 100 lbs. of extracted. While occasional yields ran away up beyond this, the average is pretty nearly as we have stated.

QUEENS INJURED BY SHIPPING.

On page 23, Jan. 1, I find: "If you and friend Doolittle are correct (and you may be to a certain extent), why is it that we have never heard more frequently of such failure of egg-laying before? Now, it is just possible that your last sentence explains the difference in our experiences." That is just it. Friend Root, of the 2000 or 3000 queens which you sell annually, these are all, except about

150 or 200 queens, of the untested ones, which are most invariably taken from a nucleus hive, in which they have never been required to fully stock themselves with eggs in order to supply their colony, as tested queens usually are necessarily compelled to do, and are usually removed to the shipping-cage while in that condition. This is very wrong. I have found that, to remove a laying queen, in the height of her laying season, from a populous colony, and ship her, generally speaking she is a failure, to a large extent thereafter, as a prolific layer. The same conditions may exist when we take a queen and cage her in a full colony for ten days, and she suffers no deterioration from it, being just as good as ever when she is liberated and gets down to business again. Therefore it has been my practice, the past year or two, when expecting to ship a queen that is in a strong colony, and a prolific layer, to either confine her to one or two frames in her own hive, or remove the hive to another stand, leaving the queen and two or three frames on the old stand for a few days before shipping her. It works like a charm—no complaint being made of queens so treated before being shipped. No matter how prolific they were before shipment, they are the same when received by the purchaser.

So, friends, never ask a queen-breeder to send you "a prolific queen out of one of your strongest colonies," as most buyers are apt to do when ordering a queen, especially if it is a tested one. Rather get a well-developed queen out of a nucleus or weak colony—one that is not overtaxed in egg-production at the time of shipment, but, rather, one that is capable of developing up to your requirements after you receive her.

Not one in a hundred, mailed from a nucleus or other small colony, have I ever had any complaint from. Queens appear to time their egg-production according to the requirements of their hives; hence in one instance it is very rapid; in the other, it is slow and more fitted to meet the requirements of shipment by mail, without loss or damage thereby.

ABBOTT L. SWINSON.

Goldsboro, N. C., Jan. 26, 1889.

I think you put it a little too strongly, friend S. While we do have now and then reports of extra prolific queens not laying at all after a trip through the mails, I do not believe that such reports come oftener than, say, two or three in every 100 queens taken right from full colonies in the height of the laying season.

WINTERING OUT-APIARIES AT HOME, AND MOVING THEM JUST AFTER THE HONEY-FLOW COMMENCES.

I wish to ask a question or two. Brother and I have about 125 colonies of bees, about half in the cellar, and half in Root chaff hives. In the spring we wish to buy 25 colonies, making 150 altogether. For the surplus-honey harvest we wish to divide our apiary, and have 75 colonies in two apiaries, 3 miles apart. Can we run all together in one yard up to within two or three weeks of the honey harvest, and then about May 15th move half of them 3 miles, so as to increase the yield of honey per colony? By having all together, we can save one man's time for nearly two months.

Our folks feel as if GLEANINGS were one of the essentials, as we have been subscribers, off and on, for twelve or more years. It seems only a few days

since I paid our subscription for two years in advance, and one of them is almost up.

We began last spring with 70 colonies, some rather weak, and increased to 125, and in July extracted pretty closely, getting about 3600 lbs. Add to this 600 lbs. of comb, taken later, makes 4200 lbs. of nice honey. We expected to feed, for winter, sugar syrup, as we can sell extracted and comb for 18 to 20 cts. per lb.; but our bees gathered, after July 25th, about 1800 lbs. more honey, enough to winter, which we left in the hives for that purpose.

Rockaway, Ohio, Jan. 18, 1889.

H. F. MOORE.

Friend M., I believe this is exactly the way that C. C. Miller, Boardman, and perhaps many others, are already managing. If your home locality is overstocked, however, your bees would not breed up quite as well if you delay removing them until the honey-yield commences.

CHAPMAN HONEY-PLANT SEED; CAN IT BE OBTAINED OF THE GOVERNMENT?

I saw the notice last spring in GLEANINGS, stating that the Agricultural Department at Washington had obtained seed of the Chapman honey-plant, for distribution. I applied to our representative, and he notified me that he had never heard of such a plant, but said that he had sent my application to the department, since which time I never heard from it. Were any of your readers more fortunate?

POLLEN BEFORE THE BIG STORM.

On the 8th of this month (the day before the big storm) we noticed a few bees come in laden with pollen of a yellow color, and this morning some of mine from chaff hives were flying before 8 o'clock. I fully concur with Dr. Morrison, of Oxford, Pa., that bees are not looked after in this section. Many that went into winter quarters with plenty of stores in the fall may be found dead in the spring.

FERTILE WORKERS, AND HOW TO TELL THEM.

Please tell me how to distinguish a fertile worker from other bees. I should like to know. I had such a colony destroy two Italian queens for me the past summer, in one hive, before I found out what was the matter with them. I then concluded the cheapest way was to sulphurize the colony. The one Italian queen they kept in the hive for 8 days, before I found her dead on the outside.

Duncannon, Pa., Jan. 17, 1889.

A. L. LANE.

Friend L., I can not help you any about procuring seed of the Chapman honey-plant. I opposed the measure of asking the Government to buy friend Chapman's seed, at the National Convention held in Chicago; also at the Michigan State Convention at Saginaw, a year ago. Some of the friends who were in favor of it admitted that the Government Seed Bureau was a big humbug any way; but they gave, as an excuse, that friend Chapman might as well have some of the humbug money as anybody else. They did not state it in just that way, but it amounted to that. Now, the \$2800 that was paid to friend Chapman for his honey-plant seed might almost as well have been thrown into the fire, in my opinion. The seed is very likely stowed away with other old rubbish, and it will probably get too old to germinate before it gets into the hands of beekeepers, if it ever does at all. Another thing, I do not believe that any bee-keeper wants a lot of Chapman honey-plant seed

until he has first tested it by trying a five-cent package; and even after it has been so tested, and the seed was wanted, I am not sure that it could be had of the Government. Perhaps I am a little uncharitable here; but I can not help feeling indignant at this whole proceeding—not only in honey-plants, but seeds for almost all other purposes. There have been a good many complaints just like yours, friend L., that they could not get the seed of the Chapman honey-plant, even after the Government had paid \$2800 for it; and it is not only this kind of seed, but seeds in general are managed a good deal in the same fashion. Our agricultural papers have for years shown it up, and protested that our money should not be wasted in such senseless proceedings, but still it goes on. This is the first time I have publicly spoken about the matter, and perhaps I shall never have occasion to speak of it again.—In regard to your last question, I do not believe that anybody has yet discovered any way of telling a fertile worker from the rest of the bees, other than the way in which the bees behave toward her. You have yourself described how we can know how fertile workers are present. The presence of two or more scattering eggs in the cells, the rearing of drone brood over worker-cells, etc., are some of the tests. For a full description of fertile workers, you had better see the A B C book.

HONEY VINEGAR NOT INFERIOR TO CIDER VINEGAR FOR PICKLING PURPOSES.

I have just read Emily West's letter, and I think I can say something in favor of honey vinegar for pickles. I don't know much about making pickles—only just a little bit, so my letter will not be very long. Last fall I made sweet pickles of green tomatoes, and made piccalilli also, making both the usual way, but using honey vinegar. They were put in the cellar in open stone jars, and are as good now as when first made. I have made tomato pickles with cider vinegar, and had them spoil in a few weeks; but these have given me no trouble whatever. I have not been successful with cucumber pickles until this winter. I always put them into cold vinegar after freshening, fixing only a quart at a time, as I knew they would get a white scum on them, and soon spoil. This fall I freshened nearly two gallons, and scalded them in the vinegar with a little sugar, enough whole cloves to give a spicy taste, and a small lump of alum. They are even better than when first pickled, I think, and the vinegar is as clear and strong as ever. The sugar gives the vinegar something to work on, and so keeps up its strength. The cloves keep the white scum from forming, and the alum hardens the pickles, making them brittle. ALICE FELLOWS.

Broadhead, Wis., Jan. 21, 1889.

HONEY VINEGAR; 10 BARRELS OF IT.

I am very much interested in bee culture (as I should be) since I have lately linked my fortune with those of an apiarian. Last year Mr. Ludden made a barrel of honey vinegar, by way of trial; and all who tried it came for more, consequently this year we have ten barrels on hand. Now, in reply to Emily E. West's article: When I came here I found that a jar of cucumber pickles on which Mr. L. had been experimenting were faring the

same as yours had. Boiling does not destroy the virtue of the vinegar, and perhaps so doing before putting on the pickles would overcome the difficulty. How old was the vinegar you used?

Shelby, Iowa, Jan. 21, 1889.

LULA LUDDEN.

The vinegar we used was white-wine vinegar; but I have been told since that it was not strong enough to make pickles to keep through the summer.

SWEET CLOVER.

I received a copy of GLEANINGS, Jan. 1st, shortly after I had written my last, and noted foot-notes on my article. I am afraid you are a little too (excuse me) enthusiastic about honey-farms of sweet clover. The point here is simply this: that, whatever dry soil will grow sweet clover, will grow alfalfa, or lucerne, and it pays better than clover, even taking the nectar into consideration. JNO. C. SWANER.

Salt Lake City, Utah, Jan. 21, 1889.

Many thanks, friend S., for your caution; but my idea was, that the sweet clover would cover the ground if the seed were simply scattered over it, without any such preparations as are needed for alfalfa; and I think this must be somewhat the case, for sweet clover makes its way through the country at large, while, if I am correct, alfalfa never does. The seed of sweet clover is so cheap that one might throw it broadcast on our unoccupied land and not be much out of pocket, even if it did not amount to much.

BEEES FROM IMPORTED, VERSUS THOSE FROM HOMEBRED STOCK.

Do you consider that imported queens produce better workers than one that has been raised here from several strains, provided they have been kept pure? or, in other words, as long as they show three bands are they just as good honey-gatherers as lately imported ones? J. T. RUSH.

Hesler, Ky.

To the question which you propound, no uniformity of answers may be expected from different ones. We think that stock direct from imported queens, as a general rule, is a little more hardy and vigorous than that produced from queens inbred so many times in our own country. The great tendency with breeders is to run for color, i. e., "nice yellow bees," "four-banded bees," etc. What we want is not color, not bands, so much as bees for business—bees that will produce big crops of honey. Our experience has been rather in favor of the leather-colored Italians as honey-gatherers, and these we generally get from imported mothers. Stock bred from queens reared in this country for several generations is pretty sure to be lighter colored; and this tendency to run to color, as we have already intimated, we are afraid has been at a sacrifice of the real bread-and-butter bees.

A QUESTION OF SETTING CIRCULAR RIP-SAWS.

I am about to use one of your 20-inch rip-saws. The business is new to me, although I am well used to hand-saws. I have an intelligent neighbor who has run sawmills near your home. He says that he sets rip-saws by sawging or hammering. Now, I admit we can get a very even set that way; but it strikes me that the hammering ruptures the

metal, makes it brittle, prevents it holding an edge, and makes it hard to file. I should like your opinion. I have read the A B C, but it doesn't cover this particular point. I like the plan there given best. I am making a saw-table, somewhat under this neighbor's directions.

WM. YOUNG.

Palmyra, Neb., Jan. 18, 1889.

Large heavy saws can be set by hammering, but it does not answer so well for small saws less than $\frac{1}{4}$ inch in thickness. You are right. The hammering, in setting, does rupture, and not unfrequently breaks the teeth. We formerly recommended the Star sawset; but as the Boynton has given so much better satisfaction, we shall recommend it hereafter. Perhaps we should remark, that the Star sets the teeth with a sharp blow. The Boynton accomplishes the same result by simply bending the teeth gently, but perhaps not quite as accurately, as the Star. Either is provided with a gauge, so that any desired set may be used. The Star set broke so many teeth that we were obliged to use something else. Since using the Boynton we have had no trouble with the same grade of saws that formerly broke. Both sets are listed in our catalogue at 75 cts. each.

WHAT MADE THEM DIE?

On Christmas I thought I would take a peep at my bees. I found that one colony had died. They were clustered, and some of them had crawled into the combs and died. There was honey all around them, and I don't think it had been cold enough to freeze them. They were in Root's one-story chaff hive. The hive was packed well, and I can not make out what caused their death; but I could not find any queen. There were two quarts or more of dead bees in the hive. Will some of you tell me what caused their death?

J. W. RUPERT.

Foxburg, Pa., Jan. 30, 1889.

It is difficult to decide just what did cause the death of the colony in question. In the absence of a queen, a colony is more apt to die. They seem to get the idea into their heads that, without a mother in the house, life is not worth living. Bad stores might have been the cause of their death. If so, then their hive ought to show some signs of dysentery.

HOUSE-APIARIES, HEXAGONAL, SQUARE, OR OBLONG.

I expect to build a bee-house this season, and write to ask if you have had any experience with bees in such a house as I propose to build.

I think this arrangement will work, but I desire to get all the information I can, before building. The squares show the hives. The spaces between the hives are 30 inches, from entrance to entrance.

Westminster, S. C., Jan. 14, 1889. R. E. MASON.

Friend M., your plan of a bee-house would work, but we would suggest that one hexagonal in form, or even square, is much better than one oblong, built as you propose making. In either one of the former, the

operator can have the extractor, etc., in the center of the building, and the steps he would be obliged to take are reduced to a minimum. Another thing, bees will find their entrance better in such a structure. We suppose you are aware that house-apia-ries have been discarded by the majority of bee-keepers. You will find their advantages and disadvantages are very well and fully covered in the A B C of Bee Culture.

STRENGTHENING WEAK COLONIES IN WINTER.

Would you advise giving a weak colony a quart or more of bees to strengthen them, or not? Does the Chapman honey-plant grow and do well in this part of Texas? What honey-producing plants or trees will be the most profitable to grow here for honey and fruit, and also just for honey?

ENOCH ANDERSON.

Comanche, Tex., Jan. 11, 1889.

Friend A., it is hard to advise for your locality. If the bees are bunched up in a small cluster, and seem to take no more space than a quart measure, they are probably strong enough. On the first few warm days they will probably expand out enough to make a respectable-looking swarm. Some of the strongest colonies here in the North are so much packed together that you would almost think you could get them into a teacup; but when a warm day comes they will fill the whole hive. If the colony you speak of is weak in reality, then perhaps it would be well for you to give them more bees, preferably from a queenless colony.—We can not tell you whether the Chapman honey-plant would do well in Texas or not; probably it would. You had better consult some bee-keeper in your locality.

CHANGING TO ITALIANS, AND BACK AGAIN TO BLACK BEES; HOW DID IT COME ABOUT?

Friend Root:—I have for a few years been a silent admirer of the Simplicity hive and your bee-literature, and now I feel like standing up and telling you how happy I am to be a member of your A B C class, and to be numbered among the thousands who are so fortunate as to be subscribers to GLEANINGS. Not unlike many other beginners, perhaps, I have had some failures in bee-keeping; but by the use of the Simplicity hive and the aid of the A B C book and GLEANINGS I have secured crops of honey which in quantity and quality astonished my "log-hive" neighbors who are apt to look upon any attempt at intelligent bee-keeping as a mere experiment or humbug.

The honey-season here for 1888 was very good.

I wish to here relate a bit of strange experience with a hive of bees—strange to me at least—on which I hope you will give a little explanation: Of the four queens ordered of you at different times, I succeeded in introducing one nicely. She proved to be a good layer, and soon I noticed my combs were well filled with brood. A little later, and hundreds of young Italians might be seen in the hive. The Italians increased rapidly, while the black bees gradually disappeared, until very few of the latter remained. Thus far I felt truly proud of my success. But soon, to my consternation, I observed that my golden-banded beauties were gradually decreasing in numbers, while the blacks were as sure-

ly on the increase. The result was, that the whole colony were again black bees.

I can now easily account for the presence of those Italians in that hive; but where did the eggs come from to produce this last lot of blacks?

Cisco, Ga., Jan. 21, 1889.

W. A. CAMPBELL.

Friend C., I think you must have left a queen-cell in the hive when you introduced your Italian queen. This queen-cell hatched, and the bees, as they do sometimes, you know, permitted both queens to live together in the hive. In due time the black queen became fertile, and may be both queens supplied the hive with eggs at the same time. Sooner or later, however, unpleasantness arose, and the question had to be decided. I think you will find the proof of what I say, by finding a black queen in your hive, instead of an Italian. I know this *may* be the case, for I have had the same thing happen. I have seen the young queen and the old one for weeks side by side, and have also, in a few cases, known the young queen to become fertile, and to commence laying, without any conflict between the two.

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

All queries sent in for this department should be briefly stated, and free from any possible ambiguity. The question or questions should be written upon a separate slip of paper, and marked, "For Our Question-Box."

QUESTION 106.—*What is the earliest date at which you regard it safe, usually, to remove your bees from the cellar, in your locality? In answering this question, make no account of exceptional weather or unusual circumstances of some seasons.*

April 1. MRS. L. HARRISON.

March 10 to 20. DADANT & SON.

About April 1st. GEO. GRIMM.

April 15, or later. C. C. MILLER.

1st to 10th of April. H. R. BOARDMAN.

From the first to the middle of April. L. C. ROOT.

I have had too little experience with cellars to name a date. E. E. HASTY.

From the 15th of April to the 10th of May, according to the season. G. M. DOOLITTLE.

We have made it a rule to get them out as soon after the middle of April as possible.

P. H. ELWOOD.

About April 10th; as soon as pollen can be gathered. I would make the date later were I to change at all. A. J. COOK.

In my locality in Iowa, the first gathering of natural pollen varied from April 6th to 25th. This is as good a guide as I know of, when to remove bees from cellar. O. O. POPPLETON.

Take your bees from their special repository, and place them on their summer stands as soon as you find that those which have been left out are gathering pollen—not before. JAMES HEDDON.

When I read this question, the first answer that came to me was, "None of your business," and I

don't know as I care to give any other; but if I don't, then what? Whoever asked that question ought to ask a few more and then quit. "Make no account of exceptional weather," etc. Well, well! the weather is what we go by here, in removing bees from winter quarters. I think Dr. Miller answered that question pretty well at Columbus. He said, "About two weeks after the right time."

DR. A. B. MASON.

I have nothing to add to the above, that I know of, except that I prefer to have them on their summer stands all winter long.

QUESTION 107.—*If brood-rearing in the spring can be controlled, would you consider it desirable to have your young bees hatch before the weather is warm enough for them to fly?*

No. GEO. GRIMM.

Some, yes. DADANT & SON.

I can never get them any too soon.

MRS. L. HARRISON.

I think not; but I don't think my opinion of much value on that point. C. C. MILLER.

I prefer no breeding till the bees are let out of the cellar about the middle of April. A. J. COOK.

I am ready to take my chances on them after they are hatched; but cold weather before is what troubles me. P. H. ELWOOD.

No. I do not think there is much to be gained, as a rule, in having brood-rearing begin to any extent before March 15th. JAMES A. GREEN.

I have had the best success in getting a good honey crop in seasons when the colonies were being rapidly strengthened by hatching brood when removed from the cellar. DR. A. B. MASON.

Never mind trying to control brood-rearing in the spring. Spend your time in a better cause. I do not consider very early spring breeding desirable. JAMES HEDDON.

I don't wish to see breeding progress in good earnest until about the middle of March; therefore I leave the entrance wide open, and make no special use of division-boards until then.

CHAS. F. MUTH.

My bees that were wintered in chaff hives in Iowa would seldom rear brood until the old bees could fly. I can not say from experience whether early brood-rearing is desirable or not; but I think not. O. O. POPPLETON.

It is a nice point to decide, as to just how early it is profitable to have brood-rearing begin (that is, if we could control it). I am well satisfied that it does not pay to have it begin any earlier than it will be continued uninterruptedly until the bees are set out. H. R. BOARDMAN.

Yes, I think it good to have the hive populous with young bees as early as their condition and instincts will admit of it, although there are seasons in California favoring early breeding so much that, when a cold snap comes, the cluster contracts enough to allow one-third or the half of the brood to perish. In such a case, less haste would have made more speed. R. WILKIN.

Yes, provided the bees are in a perfectly healthy and natural condition—and such do sometimes raise considerable early brood with profit to themselves

Abnormal brood-rearing, which seems to be merely a phase of dysentery, is a thing to be dreaded. I think the young bees so raised likely to perish without profiting the colony very much.

E. E. HASTY.

They should fly soon after they hatch. I have known some cases where Italian queens were introduced to native stocks just before placing the colonies in winter quarters; and when taken out the first of May they were very populous, and nearly all of the bees were Italians; but I think the rule is, that bees winter best which do not breed extensively in winter quarters.

L. C. ROOT.

If brood-rearing could be controlled, I would have the bees wait about it till settled warm weather came, providing that no material loss of old bees would occur before the brood hatched; but as the bees are still liable to do as they please in this matter, as they have done in years past, I do not know that it is of any use for me to express an opinion in the matter.

G. M. DOOLITTLE.

My opinion is, that the above question is a hard one to answer positively. I have had colonies raise brood almost all winter long, when well packed in chaff, and come out stronger in the spring than when they started into winter quarters; and at other times I have had them give excellent crops of honey when no brood was started until some time in March. Some years ago we had a very warm, sunshiny March—so much so that people made gardens, and the bees gathered pollen in large quantities. During that spring I had, as a matter of course, quite a number of weak colonies. Old hands advised me not to undertake to winter them; but they commenced brood-rearing in March, and gathered not only pollen, besides working on meal, but made such large patches of brood that I was jubilant. Well, during the latter part of March or the fore part of April we had a succession of cold storms that cut off the supplies and contracted the cluster, until they could not cover the brood, to such an extent that my prosperous young colonies were killed outright, almost every one of them. In this case, encouraging early brood-rearing was the death of them. Had they been kept in the cellar, or been under heavy chaff packing, where the sun could not reach them, and no meal given them in the spring to incite to early brood-rearing, they might have lived. We should remember, however, that, during most seasons, if they get along well, say as late as the first of April, they will probably be all right. These facts may help us to bear in mind what *may* happen.

QUESTION 108.—If one worker-bee, called A, stings another called B, does A lose its sting, according to your observations? If not, why?

I never observed.

MRS. L. HARRISON.

No. I don't know why.

GEO. GRIMM.

According to my observation, no. A is careful, and stings where the tissue is too frail to hold the sting.

A. J. COOK.

I have seen but one bee sting another. A queen was stung by a worker, and died immediately. The sting was left in the queen.

DR. A. B. MASON.

Not usually, because the sting is not in very deep.

DADANT & SON.

My observation is, that the bee does not lose its sting in the above case. It seems to be able to withdraw the sting.

L. C. ROOT.

If A stings B in the soft part of the abdomen, A is not apt to lose her sting; if in the breast or back, she will lose it generally.

C. F. MUTH.

One bee does not lose its sting when using it as a weapon upon another bee, because it is sufficiently strong to do the work without being injured.

H. R. BOARDMAN.

Sometimes, but generally not—very rarely, in fact. I suspect the sting is thrust into one of the breathing-holes, from which it can easily be withdrawn.

C. C. MILLER.

I never knew a bee to lose its sting by stinging another bee. I think the sting can always be withdrawn from any thing not more solid than the body of a bee.

R. WILKIN.

I have not noticed that they lose their stings. I have not investigated the matter, but have concluded the parts between the segments are soft, so that the sting may be withdrawn.

P. H. ELWOOD.

I do not know, but I guess not. Professor Cook will tell us about that. I do not care any thing about it. It is much further from apicultural dollars and cents than many other questions which I do not understand, but desire to.

JAMES HEDDON.

I have seen them sting and kill, without losing the sting; but I have seen some trying to pull away from the one stung, without succeeding. I think it depends in what part they sting, and they seem to know it, as may be observed when they are trying to sting each other.

PAUL L. VIALON.

He does not, generally, I believe. The power required to tear the muscles of the sting loose is less than the power required to lift bee B and pull him around. Even when the sting takes a firm hold of something solid, bee A can get it out by whirling around with a corkscrew rotation.

E. E. HASTY.

No. Because the sting does not penetrate deep enough so that the barbs catch and hold, as they do when thrust deeply into the flesh of an animal. I have frequently been stung so lightly myself, that the bee took its sting with it, after twisting around a little to withdraw the sting.

G. M. DOOLITTLE.

I never knew a bee to lose its sting in stinging another. I presume I have seen many thousands of bees that had been killed in this way, but I never saw a sting in one, pulled out from the body of another. I suppose this is because the sting is inserted between the horny plates of the body, which are too hard and close-grained for the barbs of the sting to catch on, while the tissues between are too soft and yielding to hold it.

JAMES A. GREEN.

Why, friends, I am surprised at you. Not one of the whole number, unless it be friend Green in the last item, has mentioned or even suggested cases where say half a swarm of bees are stung to death in a couple of hours. In fact, I have known a nucleus, containing less than a quart of bees, to sting to death an absconding swarm of two quarts or more, that tried to get into their hive, and the whole was done during a

few hours in the afternoon. Now, in this case I do not think a single bee in the whole nucleus lost a sting. The dead bees that covered the alighting-board and partly filled the hive were all blacks, and I do not remember of finding a single Italian among the mass of dead ones. In such cases they certainly do not lose their stings nor receive any harm. I have, however, seen bees, when trying to sting a strange queen, sting each other in such a way as to leave the sting fast in the dead bee. In such a case I can not see how the unscrewing operation can be put in practice at all, for the dead bee has not weight enough, and, of course, does not cling to anything, so that the one that stung him has to lug him around or loosen his sting as best he can.

NOTES AND QUERIES.

We solicit for this department short items and questions of a practical nature; but all questions, if accompanied by other matter, must be put upon a SEPARATE slip of paper with name and address.

BEES WORKING IN JANUARY.

MY bees were busy at work, Jan. 23, 24, and 25, working on the hickory stumps where clearing is being done on my father's farm. But since that it has been very cold. I do not mean the thermometer has been 40° below zero, for it has been down to only 8 above zero. My bees are in a splendid condition.

Loring, Kansas, Jan. 27, 1889. P. C. CHADWICK.

FROM 5 TO 21, AND 1700 LBS. OF HONEY.

I commenced last spring with five colonies of Italians, and increased to 21 during the season, and got 1700 lbs. of honey. I have about 40 gallons of candied honey on hand now.

A. THAMES.

Blum, Texas, Jan. 2, 1889.

TOWARD WHICH POINT OF THE COMPASS SHOULD THE HIVES FACE?

What side do you prefer for the bees to fly? I think to the east is the best, winter and summer?

Deshler, O., Dec. 3, 1888.

T. OBERHITNER.

[We have for years tried hives with their entrances facing toward the different points of the compass; and, take it all through, for a whole year, the difference is so slight that I do not think it material.]

TO CLEAN TIN HONEY-CANS.

What is the best way to clean last year's tin honey-cans that are a little rusty inside, for honey next year?

P. MULLEN.

Green Isle, Minn., Jan. 14, 1889.

[I do not know any better way to clean honey-cans, where the opening is too small for the hand to go inside, than to put in some coarse sand, and shake it about until it scours off the rust. If you can get your hand through the opening, take some sand on a cloth, and scour it bright.]

CARBOLIC ACID VS. SMOKE, FOR INTIMIDATING BEES, ETC.

I don't see any thing in your journal, about the carbolie spray. I have used it, and find it very successful. I never use a smoker now (and I never did smoke), so I am not asking for one. I find the spray the best quieter, and quickest for manipulating, and it keeps bees healthy.

J. DANN.

Wisbech, Scotland, Jan. 15, 1889.

[We have tried the carbolie-acid spray in lieu of smoke. It will answer tolerably well if the smoker

does not happen to be handy; but for real execution, smoke is far ahead. We have tried a great many substitutes; but every time we have gone back, fully satisfied that smoke is better.]

WHICH GOES OUT WITH THE SWARM?

When a swarm of bees comes out naturally, does the virgin queen come out, or does the old one come out? Which one leaves the old home or hive?

BEE-KEEPER.

[The old queen leaves with the first swarm of the season, and this rule has but few exceptions; in fact, with the Italians, a great part of the time the old queen leaves before the young one is hatched, and sometimes even before a queen-cell is built, so you see it can not possibly be the young queen, when there is not any young queen at all in the hive.]

EIGHT OR TEN FRAME HIVES—WHICH?

In handling my bees last year it seemed to me that 10 frames in the Simplicity hive were too many, as you recommend in the A B C book, both in the brood-chamber and in top story, for the production of honey. Do you still claim 10 frames as the right number in the Simplicity hive?

EDWIN HOLTkamp.

Bellville, Tex., Jan. 22, 1889.

[An eight-frame hive may be better for the production of comb honey; but for a general-purpose hive, and particularly one for extracting, we should prefer one with ten frames.]

HONEY-JUMBLES; SOUTH MISSOURI.

Will you please give a recipe for making honey-jumbles? Can you or any of your readers give me any knowledge of the honey resources of South Missouri?

S. G. PALMER.

Tobias, Neb., Jan. 4, 1889.

[The nicest honey-jumbles are made only by appropriate machinery, such as is to be found in large bakeries—at least, that is my impression.—The only way to find out about the honey resources of Southern Missouri, or any other particular locality, that I know of, is to look over the reports in the back volumes of the different bee-journals. If you contemplate moving, it might pay you to purchase all the back volumes you can find, and hunt them over. Better still, go on an excursion-trip and make inquiries.]

REPORTS DISCOURAGING.

NO LOSS DURING WINTER, BUT DISCOURAGING JUST THE SAME.

MY report for the last two years has been discouraging. I feed more syrup than I get honey; but I am not discouraged. I am going to hold on a while longer. I have been in the business four years. I have now 24 stands in good condition. I take GLEANINGS, and have your A B C book. I use your chaff hives, and I have never lost a colony yet.

Horatio, Ohio, Jan. 28, 1889. NOAH THOMAS.

NOT PAID EXPENSES; WHY THE BEES DIED.

My bees have not paid expenses for the last two years, and I am getting tired of stuffing bees and getting no stuffing. I was not at home in the fall when they should have been fed, and some of them have died with cramp in the stomach. Will you please say whether you know, by experience or otherwise, the effect of beet-sugar candy, shortened with flour, for this fatal disease? I gave them all a dose of that kind of medicine a few days ago, to see how it would work.

M. V. EWBANK.

Wheatland, Ind., Jan. 29, 1889.

Beet sugar is not equal to cane sugar for winter food—at least, the editor of the

British Bee Journal so thinks. The addition of flour to the bee-candy as a *winter* food is a little risky, even with the best granulated sugar. We recommend the admixture of flour, only for the purpose of stimulating brood-rearing in spring; but it is hardly to be advised in the dead of winter.

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from \$1.00 to \$1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows; viz.: *Sheer Off, Silver Keys, The Giant-Killer*; or, *The Roby Family, Rescued from Egypt, Pilgrim's Progress, and Ten Nights in a Bar-Room*. We have also *Our Homes, Part I, and Our Homes, Part II*. Besides the above books, you may have a photograph of our old house apiary, and a photograph of our own apiary, both taken a great many years ago. In the former is a picture of Novice, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

CONDUCTED BY ERNEST R. ROOT.

WE haven't received many drawings from the little folks yet. Haven't we got some little artists among our number who write for this department? Oh, yes! we are sure we have. Remember to make the drawing represent something useful, and remember, also, to make the picture without the aid of papa or mamma.

PA'S BEES.

My pa has 30 swarms of bees. They swarmed six times last summer. He has 11 colonies in chaff, on summer stands, and 19 in cellar. He carried them in his arms. He has the entrance the whole width of the hive, and a top entrance. He put the bees in the last of November.

WILBER L. BOYD.

North Monroe, Maine.

HOW PAPA WATERS HIS BEES.

Papa has 28 hives of bees. He saw them gathering pollen the middle of January this year. They got it from alder-blossoms. Papa had one swarm of bees last year on the last day of March, and six more the next week. I will tell you how papa waters his bees. He lets the water drip slowly from a barrel on a plank that slants downward.

Cuthbert, Ga.

JOE DUGGAN, age 9.

ABOUT A PIG.

Last winter my grandma gave me a pig. I fed it lots of corn and milk, and it got very fat. I told pa if he would get me a little wagon he might have the pig, and so he got me the wagon, which cost \$2.25, and then something got the matter with the pig's throat, and about two months ago it died. I got my pay for it any way.

ERNEST BALDWIN.

Stewardson, Ill.

PACKING-BOXES.

My father winters his bees on their summer stands. He gets a box that is larger than the hive. Between the box and the hive we fill with chaff. For the roof we use siding, and the whole amount cost 25 cents besides the work. We never lost any bees while we wintered them that way, and they seem to do first rate.

HANS C. NELSON, age 14.

Barnes, Kan.

NOT A CARP-POND, BUT A TROUT-POND, AND ONE THAT TWO BOYS MADE.

My pa hasn't any bees, but he got two colonies three years ago; and when winter came he put them in a little underground cellar out of doors. It got so damp in the cellar that the bees died. He has a sawmill, and has a lot of saws, and can saw frames and lumber for hives. He is going to get some bees by and by. He is going to get some carp also. We have a good place for a pond. My brother and I made a pond, and caught some trout and put them in it. They were from 2 to 12 inches long. They would swim around and jump up for flies. One died because the water was too warm.

ERNEST SEATON, age 14.

Ellensburg, Wash. Ter.

FOUL BROOD AND CHESHIRE'S REMEDY.

Five years ago papa had 46 colonies, and they all got foul brood. Papa tried Mr. Cheshire's remedy of "Calvert No. 1," phenol, early, on one, and then built them up to a full colony. They cast three swarms that summer. Papa hived the new swarms in clean hives, and buried the combs of the parent stand. The past season was a very poor one. We got hardly honey enough to pay for the work. Mamma hived all the swarms with the weak ones. She caged the queen that came out with the swarms, and let her run back into her own hive.

Coldwater, Mich.

IDA CARLS, age 10.

You say in your letter, friend Ida, that your papa tried Mr. Cheshire's remedy. Although you intimate that the bees were cured, you do not say so in so many words. As you are perhaps aware, this remedy was a failure with us. So far as we can observe from the letters of our correspondents, it is not very apt to be a success in the hands of any one. We should be glad to know whether the parent colony stayed cured.

WANTS A LITTLE ENGINE; PAPA'S FRAME-LIFTERS.

Papa has 8 colonies of bees, mostly Italians, in Simplicity hives. He is wintering them on their summer stands. He put the hives in boxes, and packed them with leaves and chaff. He makes his own bee-fixtures. He has a foot-power saw, but he wants a little engine very bad. I have made sections and frames alone, and they looked as well as papa's.

Papa made two hooks to take out frames with. The ring is large enough to put one or two fingers into; he puts it under the frames and lifts them out. I thought if I wrote about it you might send me a book. This is a picture of it.

Grafton, Vt.

GEORGE E. WALKER, age 11.

If your papa has many hives to make on a foot-power buzz-saw, I do not much wonder that "he wants a little engine very bad." See what we say in regard to foot-power versus steam, on page 91 of our last issue.

Your papa's frame-hook will answer the purpose, but we should very much prefer to use the fingers. We have sometimes used such an arrangement to "heft" the frame—that is, to find out its weight in mid-winter, when the day is warm enough to warrant disturbing the cluster. In lifting up the chaff cushion, burlap, etc., we find that it saves a little time to use such an implement. A little experience in lifting up at one end will tell about how much stores there is in each frame—consequently how much there is in a hive.

HOW PAPA HIVES SWARMS; NO HONEY FROM WILD CUCUMBER.

My father hives bees in this way: The bees generally alight in a low place; then he gets the table and puts the bee-hive upon that. He brushes them down into the hive, then covers them up quickly, and lets them stand until after sundown; then he moves them to their permanent places. Last summer we had a new stand of bees, and their combs broke down twice. Papa had quite a time changing them into a new hive, in order to save them. He makes his own hives. We got only a few pounds of surplus this year. Papa sends to you for his supplies. The wild cucumber seems to be a honey-plant in some places, but it is not so here, for we raise them every year. It seems queer that the bees never go near it, as it is so fragrant. I like to hear papa read your travels to California.

Waco, Neb., Jan. 26, 1889. EVERETT PHIERY.

MY BROTHER'S BEES, AND HOW WE HIVE THEM.

My brother takes GLEANINGS. He had 9 stands of bees, and they increased to 14. It was a very poor season for honey. They made enough for themselves, and we got but a few pounds of surplus honey. My brother left them out in the orchard, where they were all summer. He says they are in good order. The way we hive them is this: When they are up in the tree, so we can not reach them very well, we saw the limb off and shake them under a sheet, and thump on the top of the hive. They always go in. Once when the folks were all away but my two sisters (one of them is fourteen and the other is but nine) and two visitors, we got a looking-glass and settled the bees. I got things ready for my brother and he came and hived them. He took a bucket and shook them into it. He covered them up with a cloth, and put them under a sheet, and covered them up until they went into the hive.

JOSEPH MILLER.

Ege, Ind., Jan. 23, 1889.

GOATS; WHITE RATS, BEES, AND OTHER PETS.

I have been reading this morning in GLEANINGS the little folks' letters, which put me in the notion to write. We have 25 goats, and one of them is just as pretty as it can be. It is just 24 hours old. We have two kinds of goats, the common stock goat, and the Angora goat. I think the Angora goat is the prettiest. It is white, with long curly wool. The common stock goat is black and white spotted, and it has short wool. Mr. Root, did you ever see a white mouse? I never did, but Mr. Littleton, the doctor who put mamma's teeth up, is going to bring us some; and if you want any white rats I will try to send you some. Grandpa has 24 bee-hives, and they are doing well so far. I have one

hive of my own, but grandpa tends to it. I live with him. Ma keeps house for him, as my papa is dead. He died last April. He was sick two years. I have two brothers—a big brother and a little one. I live at Albany Switch, a little place between Henry and Paris. I go to Henry to school, and board from home. Grandpa takes GLEANINGS, and it is always a welcome visitor. I have a pet cat named Veda. When I call, it will come running as fast as it can. I like to go to school. My teacher's name is Miss Lillian Walters. She is tight, but still I don't think she is any too tight. If we talk one day we have to write one hundred words; and if we talk two days we have to write two hundred; and if we talk three days, we have to write three hundred, and so on.

LOUNETTE CARTER.

Henry, Tenn., Jan. 19, 1889.

Your letter is very interesting, friend Lounette. We thank you for your very kind offer; but as we have so many of the common kind of rats and mice, we shall hardly want to accept of their white relatives. We have seen them, and they look very pretty in their cage.

A HOME WITHOUT A PAPA.

In the spring of 1887 I wrote to you that, the summer before, we built a large hay and cattle barn, and a creamery near the well. We had been renting the fields for four years, but that year papa hired a man and ran it again himself. Papa's health seemed much better. In the fall he plowed some fifty acres with the riding-plow, which he hadn't been able to work in the field for eleven years. It seemed nice to have him well enough to be out around. He taught me much about farming; but on Jan. 6, 1888, he took a heavy cold and kept getting worse, and spitting blood every day, and April 1st he died, which leaves mamma alone with four children, and I am the oldest. We had a sale, and sold off all but what we needed for convenience. We kept two swarms of bees. They were in chaff hives. We have a great number of hives that we did not sell at the sale. Mamma says that, as long as she lives on the farm, she will keep bees. In 1888 we had to rent the farm again to four of our neighbors. I went to school six months—two in the spring and four in the fall. In harvest and haying I worked for 50 cts. a day. I earned \$21, which bought me all that I needed. This year mamma rented all the farm to our nearest neighbor. I think it is nicer than to have so many different men working the farm, because they seed down their own farm and run down the rented one.

ARTHUR J. BOSSEMAYER, age 13.

Dixon, Ill., Jan. 29, 1889.

PA'S SOLAR WAX-EXTRACTOR.

I have long wanted to get the book, Ten Nights in a Bar-room, so I am going to try to get it. I will send you a drawing of pa's wax-extractor. It is a box about a foot and a half long, a foot wide, and about ten inches deep, with a double cover. The upper cover is lined with tin; the lower cover is glass, both hinged to the box. Inside there is a screen that rests on small cleats in which you put the comb. Below this is a small dish which catches the wax. When the cover is up in a bright sunny day the heat will reflect from the tin through the glass, and melt the comb very rapidly.

Pa has 20 swarms of bees, packed in the Wolverine chaff hive, which he makes to sell. He wintered 17 colonies without loss last year. Mamma's name was Root, and she has an uncle whose name is Hezekiah Root. He lives about five miles from G. M. Doolittle. His business is bee-keeping. Grandma Root lives with us. I have a brother by the name of Huber. He is three years old. I am eleven years old.

RUEL H. RAWSON.

Quincy, Mich.

Your drawing, friend Ruel, is very good, and represents the idea very nicely; but as it is very similar to the engraving in our price list, with the exception of one or two details, it will hardly pay to have it engraved here, for everybody knows how that is made. We do not wish to carry the idea that you copied your picture from the engraving, for we are sure you did not, because of some little details. If the little folks will read Ruel's letter and compare it with the cut of our solar wax-extractor, they will get an excellent idea of the same. We suppose you know that the wax rendered by the heat of sun is yellower and nicer than that rendered by any other means.

A PAIR OF OLD SHOES.

BY EUGENE SECOR.

The daintiest white leather that ever grew
On the back of an innocent mountain kid,
With laces once red, and tassels once blue,
Make the shoes in which baby's pink toes were hid.
'Tis true, that these "booties" are out at the toe,
And slightly the worse for wear at the heel;
But new ones never can interest me so,
Nor bring to my heart such innocent weal.

Each wrinkle is prized by the mother-herd,
And reminds her of smiles on her darling's face;
Each stain is more precious than work of art,
For baby's sweet mouth these lines did trace.

For the few happy months while these have been worn,
My life has been one perpetual hymn;
Since she came to earth by kind angels borne,
My cup of joy has been full to the brim.

While these were worn, the first pearly teeth
Brought as pleasant relief as did Noah's white dove;
When the first steps were taken, these shoes were beneath
The precious load of sweetness and love.

With fond recollection I often recall
Her innocent prattle when perched on my knee,
With language so simple, yet puzzling withal,
She charmingly tried to entertain me.

As these little old shoes are tucked away,
And tenderly kept with scrupulous care,
We think of the toddling wearer, and pray
That those feet may be guided from every snare.

We pray that the Shepherd may guard this lamb,
And shelter her always in his safe fold;
May her life, like these shoes, prove not a sham,
And her worth like these, need not to be told.

TOBACCO COLUMN.

CONDITIONS UNDER WHICH WE GIVE SMOKERS TO PERSONS WHO STOP USING TOBACCO.

First, the candidate must be one of those who have given up tobacco in consequence of what he has seen and read in this department. Second, he promises to pay for the smoker should he ever resume the use of tobacco in any form, after receiving the smoker. Third, he must be a subscriber to GLEANINGS. Any subscriber may, however, have smokers sent to neighbors or personal acquaintances whom he has labored with on the matter of tobacco-using, providing he give us his pledge that, if the one who receives the smoker ever uses tobacco again, he (the subscriber) will pay for the smoker. The one who receives the smoker in this case need not be a subscriber to GLEANINGS, though we greatly prefer that he be one, because we think he would be strengthened by reading the testimonials from time to time in regard to this matter. The full name and address of every one who makes the promise must be furnished for publication.

STEPPING HEAVENWARD.

I COME to you with two new candidates for the Tobacco Column. I do not keep bees at present, but I go to Carlstadt every week to manage a farmer neighbor's bees for him. He has no smoker, so I told him about your offer. He thought it over awhile, and then said, "Friend H., I will try it right off, as I have smoked and chewed tobacco for the past eight years or so. I will also give up drinking beer, to which I have been addicted for quite a few years. If I start again, I promise to pay you all it costs."

Friend Root, I have a show to see that he keeps his promise, because I am out there every week. He is a farmer, and well to do. If he breaks his promise I will see that you get your pay.

I am the other candidate. I have given up smoking the pipe and cigar, to which I have clung about seven years. I do not need a smoker, as I don't keep bees at present; and I also have a Bingham; but I only want it to show to friends, and tell them about your offer, and see how long our promise lasts.

FRED HOLTKE.

Hoboken, N. J.

Friend H., may God bless you both in your undertaking. Most gladly do we send you the smoker to show your neighbors, and to exhibit as an object-lesson in gathering new recruits. Our readers will please notice that your friend accepted your suggestion as something in the right way, for he voluntarily, of his own free will, put his beer-drinking with the tobacco, and throws them both overboard. You may think that the heading which I put to your kind letter is a little extravagant; but, in my opinion, leaving off habits which you know to be bad is one of the surest steps toward righteousness that a man can take.

TOBACCO MONEY TURNED INTO A LIBRARY OF 300 VOLUMES.

Let me give your readers who are leaving off the tobacco habit an idea that occurred to me when I laid aside the weed nearly eighteen years ago. At that time I resolved to invest in good books the same amount of money, yearly, that I would have spent for tobacco had I continued its use. The result is truly surprising. I have now a library of nearly 300 volumes, to which I am still making frequent additions. I have often wondered if our worthy editor ever was a slave to the weed; and if a personal knowledge of the filthiness of the habit, combined with his good will to all, prompted his liberality to those who promise "to do so no more."

Mingo, O.

I. M. MARTIN.

Why, friend M., it seems as if there were a providence in having your bright cheering letter follow right along in the wake of the one above it. Who shall say there are not plain evidences of the hand of God in this Tobacco Column? May God bless you for the example which you have set before us all. No, dear friend, I never used tobacco. But there is no credit due me at all for *not* using it. It did not happen to be in the line of my temptations. Your question reminds me of a jovial friend of mine who has a comic way of declining, when a cigar is offered him. He replies something like this: "No, sir. I tell lies and drink whisky, but I never use tobacco." The laugh that this creates lets him out with a good grace. Now, I do not want to have you think that I drink whisky, or that I ever did; and I am trying very hard not to tell lies, even little ones, either by word or by act.

OLD TOBACCO MONEY TURNED INTO CHRISTMAS PRESENTS.

I am very thankful to you for inspiring me to stop using tobacco; for with the money thus carefully saved I have bought for my little girl such Christmas gifts as not many children in this neighborhood can enjoy; and, besides, I feel much cleaner and better since I no longer handle the accursed weed.

ED E. SMITH.

Carpenter, Ill., Dec. 23, 1888.

Why, friend Smith, yours too is inspiring. The money that you have been using for indulgence in a filthy habit has been transformed into useful and wholesome gifts for your little girl. Another thing, that same little girl (and may God bless her) can now climb up into your lap and give you a kiss, without any misgivings that your mouth may not be clean enough for her innocent little face to approach.

A GOOD RESOLVE AT THE END OF THE YEAR.

I shall soon be 26 years of age. I am a single man. I commenced to take GLEANINGS less than a year ago. I have purchased 11 colonies of bees, and expect to keep bees for a livelihood henceforth; but the worst of all, I have used tobacco for the last five years. I did not chew, but smoked. At last I let decency get uppermost, and on the last day of 1888 I bid adieu to tobacco in every form. So far I find it no trouble to do without, and, by the grace of God, I will never use it again. I have a brother, who is 2 years younger than I, who used the weed for 12 years in every conceivable form, and was a slave to it. Two years ago he quit it, and has never touched it since. He is going to the State University at Morgantown. We were the only ones, out of a family of 4, that used the weed. I do not charge a smoker for my little self-will, but only ask that I may have grace sufficient to enable me to overcome my bad habits.

S. RAY HOLBERT.

Watson, W. Va., Feb. 6, 1889.

BREAKING THE HABIT THROUGH GOD'S HELP.

I tried to quit using the weed in my own strength, but I failed, afterwards I tried again and prayed to God to help me and now I neither smoke or chew, or drink liquor, nor have I any desire or appetite for either.

A. W. MAKER.

Urbana, Ill., Jan. 5, 1889.

MYSELF AND MY NEIGHBORS.

The heavens declare the glory of God, and the firmament sheweth his handiwork.—Ps. 19: 1.

A NOON-DAY PRAYER-MEETING IN THE CITY OF LOS ANGELES, CAL.

MONDAY it was my pleasure to attend a noon-day service in the busiest part of the city. I got in early (did you ever know, dear friends, that a special blessing often attends those who are first on hand in God's house?) and was pleased to receive a kindly welcome, with outstretched hands. And before the meeting opened we early comers had a most pleasant little family talk. I am told that a man and his wife keep up these meetings, at their own expense. God has blessed them, and their income is sufficient so they can afford to do this work in this busy city, without pay. Yet, dear friends, it is *not* without pay, as the genial light and love in their faces attest. I was obliged to leave before the service closed, but a brother followed me to the door, and gave me some tracts, a copy of which I give below, in small type.

PROFIT AND LOSS!

IF I GET SAVED I SHALL

LOSE	GAIN
Sinful pleasure.	Holy joy.
Wicked associations.	Divine fellowship.
Ill-gotten gain.	Treasures in heaven.
Worldly wisdom.	Wisdom from above.
Heart condemnation.	No condemnation.
Doubts and fears.	Peace in believing.
Friendship of the world.	Friendship of God.
Dread of the future.	Blessed hope.
Everlasting punishment.	Eternal life.

THESE ARE SCRIPTURAL FACTS!

Since I may die any moment, I had better reckon the loss and gain just now.

"What shall it profit a man if he gain the whole world and lose his own soul?"

THE RESULT OF CHOICE IS ETERNAL!

COME TO THE GOSPEL MEETINGS

at the

NADEAU' BASEMENT.

Corner First and Spring Street.

Noon prayer-meeting from 12 to 1 daily.

Salvation meeting every night.

Sabbath services 10, 3 and 7 p. m.

To Huber.—Dec. 11—I'apa is now away up in the clouds—in the clouds resting on the Rocky Mountains. They are a great bother just now, for I wanted to see the valley below, but I can't see it at all, nor the hills above. May be, however, we shall soon get up to be above the clouds. We are now just about half a mile high; but in four hours more we shall be over a mile and a quarter *right straight up*. The railroad book tells us just how many feet high we are every time we stop.

While we are waiting to get out of the clouds, I want to tell you of something else. Last Saturday we were on Long Beach. It is called so because it is a good many miles long, and the ocean waves have washed it as clean as a stone sidewalk. The water, as it comes rushing and roaring up in great waves, is full of bright sand that shines almost like silver. Well, every wave drops some of this sand; and, what is very funny, you can walk on this clean sand with your best slippers, and not soil them a bit. My friend even drove all over the beach with three of us in the buggy, and neither the wheels nor the horses' hoofs sank a bit;

and then he drove right out among the splashing and roaring waves, until I begged him to go back. While we were there, a lot of boys and girls came down with bathing-suits on, and they just splashed right out into the ocean. They would just stand still and let a big wave knock them over, and one little girl who had a very pretty bathing-suit and bathing-hat just sat down until a big wave came up, then she tipped over back, and all we could see of her was her heels kicking about as they stuck out into the air, from the crest of a foaming wave. When she came out she looked as rosy as could be, and I saw her next day at Sunday-school. My friends wanted me to go in, but I think I like the *warm springs* best, especially in *winter time*.

Hello! the old engine has been puffing and puffing, and now the wheels have slipped so much it is standing still. We are above the clouds, and they lie below us like a great ocean. Here we can see the pine-trees on the opposite side of the clouds, so it is now like a great lake. A boy in the next seat declares it is a lake. Now we see little "puddles" of clouds settled in the low spots or hollows between the hills.

Later.—Our old locomotive has had to give it up—it is too hard climbing. The passengers are all out in the moonlight enjoying themselves on the mountains. I don't know what they expect to do.—*Later.*—They telegraphed for a "younger" locomotive (the other was an old one), and now we are just making the gravel fly as we climb up.

Dec. 12.—We are over the mountain, but still 4500 feet high. On my homeward trip I have decided to try a cheaper way of travel. I started in the ordinary coaches; and by sleeping in my seat I have saved \$3.50 per day thus far. I slept pretty well, and, were it not that I should come before my friends looking worn out, I think I should keep it up clear home. Last night I took a sleeper, \$2.00, providing I got up at 6 o'clock, which, of course, I should do any way. A nice clean bed, where I could stretch my limbs at full length, was a luxury after a night in the seats. Reader, did you ever thank God for a clean soft bed, with plenty of room? If not, do so now, and thank him that it doesn't cost \$2.00 a night.

This morning, while the passengers were loudly complaining of the poorness of a breakfast (here at Battle Mountain) that cost them 75 cts. each, I enjoyed a most delicious repast here in the car at a cost of *thirteen cents*. Shall I give you the bill of fare? A *huge* but delicious California pear, 5 cts.; crackers and cheese, 5 cts.; home-dried figs, 3 cts. The crackers and cheese were in a large paper bag, set in my open sachel, placed in the seat beside me, so I could, by holding my head over it, avoid unsightly crumbs on my seat or person. In fact, I finished my breakfast before daylight. The fruit I got of boys at the stations where the cars stop. Never buy fruit on the cars. One train-boy wanted 25 cts. for *three apples*, and was abusive because I told my neighbor that, in Ohio, we could get a *bushel* for 25 cts. I did not mean the boy should hear me. There is certainly a great

wrong in this matter of "daily bread" in traveling. When I first arrived at Los Angeles it was 11 o'clock at night, and raining hard. The hotel right at the station, and in which the Southern Pacific have located their ticket-offices and waiting-rooms, charged me \$1.75 for lodging and breakfast, neither of which was first class. A few days later I had lodging and breakfast at the oldest hotel in the city, with a pretty room, lighted with gas, and all accommodations to match, and yet the charge was only 75 cts. *without the dollar*. The extra dollar I paid was to support a gilded whisky-shop; and my friend, the man who sells liquors, may be *expected* to defraud and swindle, for he acknowledges himself devoid of conscience by the act of liquor-selling. Is it not time for good people to refuse to stop at any hotel keeping a bar? At the one mentioned, a glittering display of liquors occupies one whole side of the room for the reception of guests.

In traveling in California I have felt much better to drink no water at all, not even tea and coffee. The luscious fruit, to be had in such profusion at every season, furnishes all that can be desired to allay thirst.

Noon.—Since crossing the Rockies we find the ground and still pieces of water frozen over, and the beautiful gardens have given place to winter; but until now we have seen no snow. Strange to tell, while there isn't a particle of snow here, right over a little way, across a sharply defined line, are mountains and highlands perfectly white with snow. I have thought for half an hour we must run into the snow soon, but it still stays just about so far ahead of us. Well, I have found out why it is winter in some spots and not in others. The white mountains are the highest; and here at Wells the snow-line is sharply defined. The snow comes down just so far and no further; in fact, a farmer might plow up to where the snow commenced.

Near the State line between Nevada and Utah we see miles upon miles of a sort of fence, to prevent snow from drifting on the track. It is simply a sort of board fence leaning away from the track. They are used only where the track is lower than the ground. Sometimes they are on one side of the track and sometimes on the other, though I can't say why. At some points immense sheds, going clear over the track, and inclosing it like a tunnel, are put up. These must have cost an immense sum, even though they are evidently made of cheap lumber.

Another little mountain is white with snow, while a great big one is entirely bare. Both are close by, but the white one is just a *little* beyond. Now, as we ran up by them the white one proved to be *miles* away, and ever so much the higher; yet when I first saw them, had anybody told me the snow-covered one was the larger, but miles away, I should have called it ridiculous. Snow capping is a pretty good indication of height, I have often been told, for no one can tell by appearances.

Six o'clock, and now the monotony of the sandy old desert is enlivened by the advent

of Salt Lake itself; and it is so accommodat-ing as to come right up close to the car win-dow. We are to ride along its margin for 3 hours, for it is about 90 miles long and 30 or 40 wide. It is so heavily saturated with chemicals, principally common salt, that no fish has ever been found to live in it, nor, in fact, any kind of animal life. One of the passengers said it was reported that two pails of water will make one pail of salt; but this is, of course, an exaggeration, as the water of Salt Lake is but 24 per cent salt. Bathers say it is almost impossible to keep under water, as it is so dense. After the bath you must be rinsed in pure water.

Dec. 13.—When I first arrived in Salt Lake City I did not at once get hold of the bee-men, and began to feel almost homesick; but when I hunted up one or two, and real-ly let them know that A. I. Root was "here," it has resulted as many times be-fore, and I have had a wonderfully pleasant time. In this region, where irrigation has to be depended on for every thing, they get good yields of beautiful honey nearly every season. The story of its source is really wonderful. Just listen: Much of the ground here is so strongly alkaline that nothing can be made to grow on it; in fact, the grass and whole surface of the ground is white with the alkali. I said *nothing* would grow; but there is one exception to the rule. *Sweet clover* will grow rank and strong, and the farmers have actually been sowing it for years, and plowing it under to get rid of the "saleratus" as they call it. This has scattered the sweet clover far and wide, and this is what gives them their beautiful honey, with a flavor that is exqui-site to me, and, at the same time, unmis-takably sweet clover. This plant is among the very few that will live through the long dry season.

The hives used here are the Kidder and crosswise L., mostly; but one friend, Mr. George Woodmanse, is succeeding beau-tifully with the new Heddon hive. He makes them himself, however, and he is a remark-ably fine mechanic. The sample hive sent him by the inventor was not as accurately made as his own.

Dec. 14.—Although it rains, I have had the pleasure this morning of seeing a snow-storm on the mountains while it rained in the valley. How kind and friendly every-body seems! It was some time before I found any of the bee-men in Salt Lake, and, as I have just said, I began to get a little homesick. Mr. Swaner we found putting up a stovepipe—at least, that was what was told us. We sent word for him to finish his job and then come out in the api-ary. When introduced to A. I. Root he said he wasn't going to be mad about the stove-pipe a bit longer, and he was now very glad he didn't *swear* when it bothered him. We found Mr. Tauffer laying a stone wall for a cellar; but he too dropped his tools, got leave to lay off, and we then went for all the rest of the bee-men. We got to friend Woodmanse's just at supper time; and when I mildly protested because they commenced to make a change in their sup-per arrangements he replied, "Please don't

be anxious; we don't have A. I. Root here every day." When his mother asked me to give thanks, I tell you I got over being homesick entirely. Now, please don't feel hurt, dear friends, when I say it has been a great privilege, during this visit, to hear a blessing asked at the table. If no one else is near to ask it, I am glad to do it in my own way and after my own fashion. I like to thank God for our daily food, and I like to ask him to let his blessing rest on every household where I am entertained; and I like to ask it *out loud* too. Just a simple ac-knowledgment to the great Creator of the universe, it seems to me, can offend no one.

Well, during this visit it is not the people only who have been friendly, but the great sun, the clouds, and the mountains—yes, the winds and the rain too, seemed pleased to see me. I got interested in the clouds and mountains in New Mexico, you remember. Well, they got up a cloudburst for my entertainment. Then at Glendale the sun and rain seemed to have planned together to get up that beautiful rainbow when I was hunting that Methodist Sunday-school. Well, this morning, after I got on the cars, and was admiring the snowstorm on the mountains, the old sun seemed to say:

"I wonder if I can't lend a hand so as to please brother Root;" and in a twinkling he looked through a rift in the clouds and illumined the snowstorm, and made the mountains glitter like frosted silver; then, by way of contrast, he shone on the grass in the valley, and then skipped to the other side of the car and made Provo Lake shine so like molten silver that I almost jumped from my seat in astonishment and surprise. This is a most beautiful fresh-water lake of perhaps half the size of Salt Lake. Now, to go back, did any photographer or artist ever "take" a mountain with the sun shining through the clouds, during a snowstorm?

I have not seen a snowflake (close by) since I left home; but just now the cars have taken a turn and started through a pass in the mountains. As soon as we got partly in, I knew of another reason why snow is on some mountains and not on oth-ers—the *wind* has a hand in the matter. In fact, wherever the east wind came through the gap, and struck, the ground was frozen. A range of mountains makes winter on one side and summer on the other. When we got through, the ground was all white; and as we ascended the canyon the streams be-gan to be frozen over. Well, we have been several hours running up this canyon to the summit; that is, to the point where the mountain stream ends and a new one com-mences on the other side of the range. You can scarcely imagine with what interest I watched the whole matter. When we started up the canyon the stream was al-most a river; but it gradually dwindled down until I saw it disappear entirely, and nothing was left but some willow-like bush-es. While I was watching for another stream and canyon to start down the oppo-site side of the mountain, the cars ran into a snow-shed and stopped observations. These snow-sheds were almost as tight and dark as a tunnel. The conductor said

they had closed it up for winter. When we got out of the tunnel the new canyon had commenced, or, rather, one ran into the other. On the extreme summit of the range of mountains there was quite a piece of ground that was comparatively level, covered with pine-trees. Of course, the cars ran through the lowest point, so that there was no chance to look miles off and down into the great valley. And not once, in climbing these great mountain ranges have I seen a place to look clear into the lowermost valley. One mountain peak rises above another so gradually that, even if you get to the top of a peak (which one never does on the cars) you see but little more than neighboring peaks. When a single mountain rises out of the plain you can easily get a view of said plains; but not so with the peaks of a mountain-range. Single peaks seldom go over a quarter of a mile above the plains, while mountain ranges are two or three miles higher than the sea-level. Going up the mountains we found many charcoal-pits for burning charcoal for the smelting-furnaces in the vicinity of Salt Lake. The principal metal ores worked are lead and silver. The charcoal is burned in permanent kilns, resembling an egg in shape, with the large end down.

Just before dark we came to the wonderful rocks called Castle Gate, close by the station of the same name. A very good-looking wall with straight and almost smooth sides, juts out from the mountain, and comes close up to the track. Now, there is nothing so very wonderful about this were it not for the fact that this wall is from 500 to 800 feet high; still stranger, a sort of tower runs up its straight outer edge, and this is further ornamented by an enlargement on the extreme top, resembling a turret. On the opposite side of the track, but a little further up, is a similar one, smaller in size. If viewed from the right spot, it is exactly like

a picture which is made from a photograph. By the dim light of the moon we had, a little further on, several views of the terraced mountains. These have a flat top, some of them a mile or two long, and perhaps half as wide, and, stranger still, the sides are beautifully terraced with a series of level shelves clear around. These shelves

CURRICANTI'S NEEDLE AND THE BLACK CANYON OF THE GUNNISON.

may be 25, 50, or 100 feet from step to step. While the mountain is oval in shape, it seems hard to believe it is not some gigantic piece of engineering and architecture.

During the day we saw huge mountains, with their rocky side looking as if some monster giant had hacked it with a huge butcher-knife, the hack-marks crossing each

other at an oblique angle. Other mountains were decked all over with great clock-shelves, with nicely rounded corners. These wondrous changes in the mountains and desert remind me of the way the women-folks used to make different patterns of patchwork. They were always studying up something new and different, and then holding it up to see if we didn't think it pretty. Well, dame Nature has been holding up lots and lots of things to me in just that way, and I want to respond, "Yes, they are *all very pretty indeed.*" How wondrous are thy works, O Lord!

Dec. 16.—Last night we passed the celebrated Black Canyon. It was in the night time, and no moon; but I got permission to stand on the platform, and, with a little explanation, I got a glimpse of most of it. It is about 15 miles in length, and the most of the way the Gunnison River has a path straight through solid mountains. We can not say the river cut it, for I am told that, on each side, the ragged edges of the precipices are so near alike no one can escape the conclusion they were once united. How, then, did this great rent come, separating them from 50 to 100 feet or more? The books tell us it was probably a "season crack," or "check," in this earth of ours. The water then flowed into the chasm, filled it up, then wore it more or less by using it as a water-course. Just about half way through the canyon is Currecanti's needle, apparently a slice, or splinter, that stood almost between the two at the time of the great crack. Some of the cliffs are said to be 2000 feet high, or nearly half a mile.

Just look at some object that you know is about half a mile away, and then imagine the rocky cliff in the picture that distance, almost straight up, and you have some idea of the scenery through the Black Canyon. When you stand in front of the needle, and look at it, you might be somewhat disappointed, for it looks more like a great mountain than a needle; but, do not be in haste to condemn the guide-books; wait a little until the locomotive takes you around the curve so you can look at it edgewise, and then you will find that, at the proper spot, it looks more sharp and splinter-like than it does in the picture on the opposite page. A single sentence from one of the guide-books, called "The Crest of the Continent," describes it better than any language of my own would do:

In the very center of the canyon, where its bulwarks are most lofty and precipitous, unbroken cliffs rising two thousand feet without a break, and shadowed by overhanging cornices,—just here stands the most striking buttress and pinnacle of them all,—Currecanti needle. It is a conical tower standing out somewhat beyond the line of the wall, from which it is separated (so that from some points of view it looks wholly isolate) on one side by a deep gash, and on the other by one of those narrow side-canyons which in the western part of the gorge occur every mile or two. These ravines are filled with trees, and make a green setting for this massive monolith of pink stone whose diminishing apex ends in a leaning spire that seems to trace its march upon the sweeping clouds. Straight as a plummet's line, and polished like the jasper gates of the Eternal city, rise these walls of echoing granite to their dizzy battlements. Here and there a promontory stands as a buttress; here and there a protruding crag overhangs like a watch-tower on a castle-wall.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, OHIO.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, FEB. 15, 1889.

The statutes of the Lord are right, rejoicing the heart; the commandment of the Lord is pure, enlightening the eyes. PSALM 19: 8.

"METHOD OF REARING EARLY QUEENS."

THIS is the title of an 8-page pamphlet, written by G. M. Doolittle, and published by E. L. Pratt, Marlboro, Mass., editor of the *Queen Breeder's Journal*. The plan is succinctly stated, and will produce good queens. The price is 5 cts., and the work can be obtained of the publisher.

ANOTHER ENGLISH BEE-BOOK.

THE "Book of Bee-keeping" is the title of a new work by W. B. Webster, and published by L. Piccott Gill, 170 Strand, W. C., London, England. The book contains 98 pages. The matter is well arranged and illustrated, and fully up to the times. It is sold at the very low price of one English shilling, or 25 cents of our money. It can be obtained of the publisher, as above.

DEATH OF WILLIAM RAITT, EDITOR OF THE BEE-KEEPERS' RECORD.

OUR good friend laid down the cares of this life, in obedience to the call of the Master, Jan. 9. An extended notice of his death should have appeared in this issue, but it is unavoidably left out. Friend Raitt was not only widely known and loved in England, Ireland, and Scotland, but, by his genial writings, to a considerable extent throughout the United States. He loved bees, but he loved his Maker and his fellow-men more; and while we feel sad to lose him from among us, we can rejoice that what is our loss is his gain.

THE GOVERNMENT SEED BUREAU, AND THE PROSPECTS OF ITS BEING ABOLISHED.

WE notice by the Boston *Herald* of Feb. 1 an exposure of some of the frauds connected with the matter to which I have alluded on page 000. We extract as follows:

Mr. Burnett showed that, through the members of the House, there were distributed last year 253,739 packages of turnip seed, and of other seeds the following number of packages: Tobacco, 89,107; grass seeds, 9679; cotton, 4023; corn, 3943; sugar beet, 2992; sorghum, 2750; oats, 2088; quarts wheat, 354; quarts millet, 26.

Turnip seed was the cheapest in the lot. That was the reason why it has been in such quantities. Millet, one of the most valuable of the fodder plants, which has only within the past few years attracted attention, was scarcely used at all.

We also take the following:

Unless the action of this morning is rescinded at a future meeting of the committee, or the bill amended in the house, there will be but one more year of the present bad practice of distributing seeds through the medium of members of Congress.

Now, I want to call attention to the matter of distributing seeds of tobacco; and I also want to take our agricultural papers to task for publishing ar-

ticles on tobacco-growing. At the same time, and in the very same paper in which these articles are published, the editors frequently give us editorials in reference to the harm that tobacco is doing in our nation. Well, where is the consistency in passing laws to prohibit the use of tobacco among minors, and at the same time distribute 89,107 packages of seed? In the same line, how can an editor warn his readers against the pernicious effects of tobacco, and then in another column give long articles teaching how to grow crops of it successfully? If new and valuable seeds are turned over to our experiment stations in all the different States, they will, without doubt or question, do good. I feel under great obligations, not only for seeds I have received from our experiment station, but for the help they have given me all along in my work of testing garden seeds.

THE ROCKY-MOUNTAIN BEE-PLANT.

SAMUEL WILSON, in his seed catalogue for the present season, gives a picture of what he calls the Mexican honey-plant, or *cleome integrifolia*, and labels it the greatest discovery of the modern age. Now, there may be different varieties of *cleome integrifolia*; but the blossoms pictured in the above catalogue have very little resemblance to our well-known Rocky-Mountain bee-plant. We have raised this plant for years on our grounds, and, as our readers are very well aware, we have for years sold the seed at 5 cents per package. As friend Wilson has always been considered a good and responsible seedsman, we can hardly understand why he should make this mistake. Very likely, however, it is no worse a mistake than many of the colored pictures of some of our new vegetables. In the first place, the picture is not at all correct, as compared with the cleomes that grow in our gardens; neither is it like the Rocky-Mountain bee-plant that I found growing in its native state on the Rocky Mountains. The illustration shows the flowers literally dripping with honey. This, too, is a great exaggeration. The plant bears honey in the morning, much as the spider plant does; but I am sure never in any locality just as it is pictured. The leaves and unopened blossoms are pictured very correctly. We quote the following from the closing remarks in regard to it:

Mr. Jesse Frazier, one of the largest apiarists in the United States, and one of the most prominent and reliable citizens of Fremont Co., Colorado, says: "No other plant known to the civilized world can vie with the *cleome integrifolia* in producing honey as food for bees. And no other honey is as clear and of as good quality." He further says, "I have frequently weighed my bee-stands for a number of mornings and evenings, and found many of them to increase as much as 9 lbs. a day."

Still further on he says:

As yet the seeds of this valuable plant are very scarce. Our agent, after traversing the mountains of Mexico for nearly two months, procured only about 100 pounds. Single packet, 25 cts.; 5 packets, \$1.00. Each packet will have directions for cultivating, and contain seed enough to plant a row 60 feet long, which will produce sufficient honey for one colony of bees.

Now, it is possible that Mr. Frazier has, in Colorado, received as much as 9 pounds of honey in a day from a single colony, all gathered from the Rocky-Mountain bee-plant; but it is a mistake in saying that a row of plants 60 feet long will produce sufficient honey for a colony of bees; neither are the seeds scarce or high-priced. Many of our subscribers have wanted to sell us the seed for several

years past, and the price has at no time been more than 15 cents an ounce or \$1.25 a pound. We are told that other catalogues have the same colored plate and the same string of extravagant statements.

SPECIAL NOTICES.

ADVANCE IN THE PRICE OF PUMPKIN SEEDS.

Last year we sold pumpkin seeds for \$1.50 per bushel; but as we are not able to buy them at that price now, we have been obliged to advance the price to 75 cts. per peck, or \$2.50 per bushel.

Prof. Cook has just finished an appendix to the Maple Sugar book, which will be pasted in the back of all that are sold after this date. Our customers who have already purchased the above work can have the appendix by making application on a postal card.

HENNIS' FRUIT AND VEGETABLE PRESS.

On pages 130 and 131 of this number is a description of the above utensil. In giving the price of it, however, the types say 25 cents, when it should be 35. Please remember this advance of 10 cents when you order.

DISCOUNTS FOR EARLY ORDERS.

Any of our readers intending to purchase supplies soon will do well to notice that the special discounts we allow for early orders are good only until March 1st, two weeks longer. If you have decided upon what you want, take advantage of the discounts by ordering at once. Your orders will receive prompt and careful attention, and you will get your goods in ample time to have them ready for the bees.

AMERICAN CHESTNUTS.

As these were very plentiful during the past season in our vicinity, they are now offered at lower prices than ever known before. To the friends who live where chestnuts do not grow, and are not common, they may be quite a novelty. They will surely please the children, if nobody else. We can, until further notice, furnish them at 5 cents a pint; 8 cents a quart; 50 cents a peck, or \$1.75 a bushel. If wanted by mail, add 10 cents a quart. To show you that they are good, we will mail you a sample package for 5 cents.

WANTED—AN EARLY YELLOW PUMPKIN.

Every season we have a demand for pumpkins—that is, the old-fashioned yellow ones—long before we can get them; and last year the people of our town would pay a bigger price per pound for a yellow pumpkin than they would for a Hubbard squash or even for a watermelon. Now, then, who has got the seed of a small-sized early pumpkin? Why, I have actually been thinking of starting some pumpkin-vines in the greenhouse, so as to have yellow pumpkins on the market before any farmer could bring them in. By accident we had a few extra early ones two or three years ago. They grew on the "New Agriculture" grounds. They sold readily at good prices, before any were to be had elsewhere; but it did not then occur to me that there was an opening for a new industry. Now, our people say they would rather have a yellow pumpkin to make pies of than any sort of squash, so do not offer us a squash, saying it is just as good. It would not fill the bill unless it looks like a pumpkin and is a pumpkin. Now, I have much faith that GLEANINGS will find something that will just fill the bill—just see if it doesn't.

PRICE LISTS RECEIVED.

Price lists have been received from the following:
Frank A. Eaton, Bluffton, O., sends out a price list of fowls, bees, and queens.
E. Kretschmer, Coburg, Ia., sends us a list of bee-supplies in general.
H. E. & E. L. Pratt, Marlboro, Mass., send out a list of Italian and Carniolan queens.
J. W. K. Shaw & Co., Loreauville, La., have issued their regular list of Italian queens, etc.
J. Nebel & Son, High Hill, Mo., send out an 8-page list of Italian bees and queens.
F. A. Snell, Milledgeville, Ill., issues a 16-page list of supplies, Italian bees, etc.

J. E. Shaver, Friedens, Va., sends us a 24-page list of bee-keepers' supplies.
B. F. Carroll, Blooming Grove, Texas, sends us a 4-page list of poultry and Cyprian bees.

We have just printed for J. P. Caldwell, San Marcos, Texas, a 6-page list of bees, queens, and supplies.

Our printers are now at work on Oliver Foster's annual price list of bees and supplies. Send for a copy, send for a copy.

CONVENTION NOTICE.

The bee-keepers of Buchanan County, Mo., met at Agency Ford, on the 2d instant, and organized the Agency Bee-keepers' Association. Our next meeting will be held on the last Saturday in March. J. G. GRAHAM, Sec'y.

The eleventh annual meeting of the Texas State Bee-keepers' Association will be held at the bee-farm of Vice-president W. R. Graham, Greenville, Texas, May 1 and 2, 1889. B. F. CARROLL, Pres't.

MISTAKES.

In the BEE-KEEPERS' REVIEW for Feb., the veterans "own up" to the mistakes they have made, and point out those being made at present by other bee-keepers. This number also has a long article from Byron Walker, showing how bees may be obtained in the spring very cheaply, and in large quantities from the South.

Price of the REVIEW, 50 cts. a year. Samples free. Back numbers furnished.

The Production of Comb Honey is a neat little book of 45 pages; price 25 cts. This book and the REVIEW one year for 65 cts. For \$1.00 the REVIEW will be sent two years, and the book "thrown in." Stamps taken, either U. S. or Canadian.

Bless Your Souls!

My brother farmers, why pay 10 or 20 cts. for a seed catalogue, when you can receive one containing just as many and very probably more varieties and all new vegetables that are really valuable, for just **NOTHING**? It may have less paint about the covers, but, great Scott! we are not after paint, but seed, fresh and true to name, such as will make with a master's hand its own picture all over our farms and gardens; seed I am not afraid to **WARRANT** on the cover of my catalogue. Come, my fellow farmers, and join the thousands, who for thirty years have been users of my seed; why, we were a goodly company and having pleasant times together before the great majority of the present race of seedsmen (bless the boys!) had left their nurse's arms! Send for a catalogue.

JAMES J. H. GREGORY, Marblehead, Mass.,

Wants or Exchange Department.

Notices will be inserted under this head at one-half our usual rates. All ads intended for this department must not exceed 6 lines, and you must say you want your ad in this department, or we will not be responsible for any error. You can have the notice as many lines as you please; but all over five lines will cost you according to our regular rates. This department is intended only for bona-fide exchanges.

I am going to Montana, and will therefore sell at low figures my apiary of 75 colonies of Italian bees, in lots or by the single hive.

A. A. FRADENBURG,

Port Washington, O.

BEE - SUPPLIES

AT DIFFERENT PLACES,

TO BE DISPOSED OF AT A SACRIFICE.

These are all new and first-class goods, which, for various reasons, are on our hands, away from home; and to dispose of them we offer them very low. If some of our readers, not far from where the goods are, need them, this is a good opportunity to get a bargain. Indicate which one you want, by the number as well as name.

No. 1. At Eureka Springs, Carroll Co. Ark.
100 wide frames, to hold eight 1-lb. sections. Value \$2.00. Will sell for \$1.50.

No. 2. At San Marcos, Hays Co., Texas.
5000 prize sections, $5\frac{1}{4} \times 6\frac{1}{4}$ high. Value \$30.50. Will sell for \$17.00.

No. 6. At Lawrenceburg, Tenn.
One No. 1 Honey-extractor, for frames $11\frac{1}{4} \times 12\frac{1}{2}$ or less in depth. Value \$6.00. Will sell for \$4.50.

No. 7. At Yorktown, Delaware Co., Ind.
11 Heddon slatted honey-boards double bee-space. Value \$1.00. Will sell for 75 c.

No. 9. At Higginsville, Mo.
One 4 H. P. engine and boiler complete, used only five months. Worth new, \$275. Will sell for \$195.

No. 11. At Johnson City, Washington Co., Tenn.
One honey-extractor that will take frames $11\frac{1}{4} \times 16$, or smaller. Value \$7.00. Will sell for \$5.00.

No. 16. At Lochiel, Ind.
20 slatted honey-boards to use between brood-chamber and T supers on Simp. hives, bee space top and bottom as we now make them. Value \$1.90. Will sell for \$1.50.

No. 17. At Berlin, Wis.
One 36-inch Exhaust Fan, second hand. It was used about 8 years in our factory. Boxes have been re-babbitted and the fan is in first-class running order. A new one this size is worth about \$100.00. We will sell this for \$25.00. It is a bargain to the one who is in need of one this size.

A. I. ROOT, Medina, Ohio.

HONEY COLUMN.

CITY MARKETS.

KANSAS CITY.—*Honey.*—The supply of honey is large; demand light; we have no change in prices.
Feb. 22. CLEMONS, CLOON & Co.,
Kansas City, Mo.

St. LOUIS.—*Honey.*—Very dull market. Mild weather interferes with sales. No demand, except from local bottlers. Quotations same as last.
Feb. 22. D. G. TUTT GRO. CO.,
St. Louis, Mo.

COLUMBUS.—*Honey.*—Very little good stock on the market, and little demand. Sales slow, and scarcely any moving; asking 17 for No. 1 white, in 1-lb. sections. No market for any other.
Feb. 21. EARLE CLICKENGER,
Columbus, Ohio.

CINCINNATI.—*Honey.*—There is nothing new to report since our last. No overstocking of the market by any means, but demand is moderate only. We quote extracted honey at 5@8 on arrival. Comb honey, 12@16, in the jobbing way.
Beeswax.—Demand is good at 20@22 on arrival for good to choice yellow. CHAS. F. MUTH & SON,
Feb. 21. Cincinnati, Ohio.

DETROIT.—*Honey.*—Best white comb continues to be quoted at 16@17 cts. Extracted, 9@10; few sales.
Beeswax, 22@23. M. H. HUNT,
Feb. 22. Bell Branch, Mich.

ALBANY.—*Honey.*—Like all other produce is moving off better again at—Buckwheat, comb, 10@12; clover, comb, 10@15; extracted, buckwheat, 6@7; extracted, clover, 7@8.
Feb. 15. H. R. WRIGHT,
Albany, New York.

FOR SALE.—I have a quantity of extracted honey in 50-lb. kegs, which I will sell at the following prices: 8c for the white and 7c for the amber, f. o. b. The honey is first-class. C. H. STORDOCK,
3-6db Durand, Ill.

«New Orleans Apiary.»

Early Queen Orders booked now for Italian or Carniolans. Warranted purely mated and safe arrival guaranteed. Address
4tfdb J. W. WINDER, New Orleans, La.
In responding to this advertisement mention GLEANINGS.

SECTION PRESS.

PRICE \$2.00.

For putting together one-piece sections. Every section square, and a smart boy or girl can fold 100 in six minutes. Try one and you will never regret it. Send to your supply dealer or to
5-16db
WAKEMAN & CROCKER, Lockport, N. Y.

1889. 19th Year in Queen-Rearing. 1889.

ITALIAN QUEEN-BEES.

Tested queen, in April, May, and June.....\$1 50
Untested 80

Sent by mail and safe arrival guaranteed. Also nuclei and full colonies. Eggs of Pekin ducks—White and Brown Leghorns, and White-crested Black Polish chicks, \$1.50 per dozen. Address

W. P. HENDERSON,
5tfdb Murfreesboro, Tenn.
In responding to this advertisement mention GLEANINGS.

CARNIOLAN BEES.

A young queen, March, April, and May, \$2. June, July, August, \$1.50; Sept., Oct., \$1. A full colony in an original Carniolan hive, March, April, and May, \$5; Sept., \$4.50. Money must be sent in advance. No guarantee on shipment by mail. Queens sent by express, which die in transit, will be replaced if returned in a letter.

MICHAEL AMBROZIC,
In Moistrana, near Lengenfeld,
5d Carniola, Austria, Europe.

J. M. YOUNG, OF ROCK BLUFFS, NEB., is now moving his apiary to Plattsmouth, Neb. All his customers and bee-keeping friends will take due notice, and address him at Plattsmouth, Box 874, Cass Co., Neb. 5d

LANGSTROTH.

In the BEE KEEPERS' REVIEW for March will be begun a comprehensive review of "Langstroth on the Honey-bee, Revised by Dadant." It will be continued through several numbers. If you wish for the cream of this work, to learn what it contains new, to know what few points the REVIEW opposes, subscribe at once for the REVIEW. The March number does the best that can be done in answering the query: "Which are the best bees?"

Price of the REVIEW, 50 cts. a year. Samples free. Back numbers furnished.

The Production of Comb Honey is a neat little book of 45 pages; price 25 cts. This book and the REVIEW one year for 65 cts. For \$1.00 the REVIEW will be sent two years, and the book "thrown in." Stamps taken, either U. S. or Canadian.

W. Z. HUTCHINSON,
613 Wood St. Flint, Mich.
In responding to this advertisement mention GLEANINGS.

FOR SALE.

UTIFITS for making 2-OUNCE SHAVING SECTIONS, consisting of one Form and a sample Frame of 20 sections made up, ready to lift off the Form; also enough Veneer to make 1000 Sections. All packed and delivered at the Express Office, for \$2.50. Address **W. HARNER,**
5d 411 Eighth St., MANISTEE, MICH.

In responding to this advertisement mention GLEANINGS.

I HAVE 80 ACRES OF CHOICE FRUIT LAND within half a mile of Sweetwater Dam station, which I will sell in alternate 5-acre tracts at \$30 an acre, cash; no irrigation required. Address 5d M. S. ROOT, Box 711, San Diego, or call at the ranch.

SECTIONS AND FOUNDATION CHEAPER THAN EVER.

Sections Only \$3. Dealers write for special prices. Free samples and price list. 1-2db
(Near Detroit.) M. E. HUNT, BELL BRANCH, MICH.

than 90 cts. each. Sent postpaid, in the
U. S. and Canadas. To all other coun-
tries of the Universal Postal Union, 18
cts. per year extra. To all countries
not of the U. P. U., 42 cts. per year extra.

OUT-APIARIES. NO. III.

DISTANCE APART.

IF you have only one apiary, you may not feel greatly interested as to the proper distance at which to locate apiaries but when you come to locate your first out-apiary, you will give the matter at least a little thought, but only so far as to feel safe that the two apiaries shall not seriously interfere. When, however, you contemplate any thing beyond the first out-apiary, the thought will likely occur that you do not know just where the limit may be, and that you may as well plan quite a little ahead, and then you may become intensely interested to know just how far apart a series of apiaries should be planted. If the field is all clear to an indefinite distance, you can plant them ten miles apart and feel easy; but then the distance to travel from one apiary to another would be quite a serious matter. So the thing you will be interested to know is the least possible distance at which they may be planted without interfering much, for a little interference at the outskirts of each range, where the flight is longest and the bees fewest, will be more than compensated by the shorter journey from one apiary to another. Just exactly what is the largest profitable range to allow an apiary, and the most profitable distance at which to plant a number of apiaries, is probably known to no one, and it is not likely that any one will ever have positive knowledge about it.

On planting my first out-apiary I supposed I

should have it about five miles away; but as a matter of convenience I made it three, and I have gradually come to the conclusion that three may be about right—a conclusion that is confirmed by the experience of others. I asked my friend Capt. Hetherington, "About what is a fair distance apart for apiaries?" He replied, "Our own are located at about an average distance of three miles. In locating we are governed in a measure by the lay of the land—the bees will make longer flights, and gather honey to greater advantage, when they follow the valleys. I think few bee-keepers appreciate the importance of this consideration." I confess I never thought of it before, and I have no doubt the captain is right.

P. H. Elwood gives an answer that does not conflict. He says, "I think about three miles. It depends somewhat on the lay of the land. I have an apiary two miles from home, in a parallel valley. Hetherington has one a little less, on the brow of a steep hill."

In addition to the "lay of the land," other considerations may have something to do with the matter of location; but in order to get at a general rule we will consider the country a dead level, uniform in every respect. The first thought may be to plant an apiary first north, then south, then east, then west. That will not do. It must be remembered that the range of flight from an apiary is in the form of a circle, not a square. In the next issue we will speak of this same matter further.

Marengo, Ill.

C. C. MILLER.

HOW DO BEES RIPEN HONEY?

FRIEND DOOLITTLE GIVES US THE RESULT OF HIS OBSERVATION, AND DRAWS SOME CONCLUSIONS.

A FEW days ago a friend called in, and, while talking about bees, honey, etc., as most bee-keepers will when they get together, he said to me, "What do you think of the idea which some advocate, that bees can not properly ripen their honey when it is stored in deep cells or in old comb?"

I replied something like this: That I did not think that the advocates of such a theory had any solid ground to stand on in advocating it; for, unless I am greatly mistaken, bees reduce their thin nectar, as brought in from the field, in just the same way in this, the nineteenth century, as they did thousands of years ago, before each bee-keeper had a sheet of foundation to place in a section so that they might have it all so handy for the heat to pass over shallow combs. If nectar can not be properly evaporated in deep combs, what have the poor bees done all of these thousands of years, previous to the advent of foundation, to get their honey fit to live on after the first year in which they built their combs, as at that time they had their new combs to build, so of course had shallow cells. Then how comes it that, as a rule, we find a much better grade of honey in old hives in the fall of the year than we do in hives having all new combs? for every bee-keeper whom I have ever talked with on this subject has been free to admit, that the best honey he ever ate came from combs which had been in the hive for some years. It seems to me that the reason for such a theory about shallow cells ripening honey better than deep ones has been sprung on the public from an ignorance of the principle by which the bees reduce their nectar to the thick honey which we find in all hives after it is sealed. Honey is so manipulated by the bees, that the change from raw nectar to thick honey comes through the manipulation rather than by its being stored in shallow cells; hence the depth of the cell in which it is stored has nothing to do with the matter whatever. Let us look inside of a hive during a large basswood yield, and see if we can not learn something. It is now 2 o'clock P. M., and we find that, in handling the combs, if we hold them a little out of perpendicular the nectar will run out, while a sudden jar daubs things generally by the amount which falls from them. When we handle the brood-combs, an examination will show us that, scattered all through the brood, are cells of this thin honey. If we now handle the sections, we find that, although they are nearly all unsealed, very little honey will run out of them, and none from the deeper cells, which are the ones from which it should flow, if there be any thing in the theory that honey evaporates fastest in shallow cells. Now come with me to this observatory hive. You will remember that, when we were here at 9 A. M., we saw every bee which came in with a load of honey give it to another bee, instead of putting it into a cell, as we are told that field bees do. You will also remember, that these bees which took this nectar from the field bees seemed to hold it, for we saw very few of them putting their heads into the cells. Now we see them taking the nectar the same; but instead of holding it as before, we see these inside workers putting their heads often into the cells,

and find honey in the midst of the brood the same as we did at the other hive, while at 9 A. M. these same cells were empty. By this you see that as long as the young bees could hold all of the nectar gathered by the field bees, they did so; but when more honey than this came in, these young bees were obliged to place it in the cells, and in doing so they used the empty cells in the brood-combs first, which are scattered around among the brood; while if they are still further crowded they will next use the store comb; and when the rush of honey is very great I have known them to put it in an empty comb outside of the hive, in some instances where I left such a comb by carelessness, near the entrance. Night comes on, and we light a lamp and go to our observatory hive. Now lie down in such a position that you can keep steady for quite a length of time. Do you see those bees which are facing this way, yet hanging by their legs to other bees? Do you see them straighten out their proboscis and draw it back again? and do you see that drop of nectar sparkle in the light when the proboscis is thrown out? What do you suppose they are doing? Suppose I tell you that they are only allowing the heat to pass over shallow cells, so that the nectar may be ripened, will you believe me? No, you would not. Well, what are they doing? for you see that all of the bees thus hanging are at this kind of work. Oh! it has just come to me. These are the "loafing bees" we hear so much about, which always hang around in all of the pretty lounging-places which are left between the combs and between the ends of the frames and the hive, which the advocates of closed-end frames tell us about, which should not be; at least they say so. Well, joking aside: These bees are evaporating nectar in the good old-fashioned way, just the same as they did it when Adam and Eve dwelt in a garden, when God pronounced all of his works good, and it doesn't matter how much you try to help them by giving shallow combs, for they will always do it the same, just to be contrary, I suppose. Now, come to this hive which has sections on, closed up at the sides with glass. Don't you see the same thing going on here, only to a far greater extent? Many a night have I lain by the side of a hive, witnessing the bees thus reduce the thin nectar brought in during the day, so that it would be fair honey in the morning. Don't believe it? Well, what are they doing then, and what is the reason that, in the morning, before any more nectar of any amount comes in, none will jar from the combs as it did yesterday afternoon? and why do we see plenty of young bees putting honey in the cells in the morning, which honey is of very fair consistency, when none at all is coming in from the fields? We must account for this in some way, and I firmly believe that the process which we have seen is the way the bees have of reducing their nectar to honey. Of course, the heat of the hive has much to do with it, for, as the nectar is thrown out on the proboscis, it needs heat to carry off the particles of water, which more readily float away from these small drops of honey which are being thus stirred over than would be the case were the whole mass in cells, whether deep or shallow. Now come into my honey-room and see if you can tell which sections were full of comb when put on the hive, and which had only foundation in them. What! can not tell? Neither can I, except as the sections in which the combs were are seen to have a little

more propolis on them; and after years of careful watching I fail to see any difference as to which will grow watery, or sweat the quickest; and I know that I can get one-third more honey from a hive having comb supplied them than I can from one which has only foundation. All will sweat if the honey-room is damp and of a low temperature, while all will be growing better if the room is kept right. Reader, while the above is not well written there is more truth than poetry in it.

G. M. DOOLITTLE.

Borodino, N. Y., Feb. 18, 1889.

Friend D., it is very certain that bees do, during the night time, get rid of a very large amount of water contained in the nectar as it is brought in from the flowers. When the hive is large, and the colony very populous, with the cracks and joints all closed, so there is no ventilation except at the entrance, I have seen a pool of water collect around the entrance on the alighting-board, sufficient for the bees to fall into when they started out in the morning. This occurs especially after a cool night, so that the alighting-board becomes so cold as to condense the moisture from the warm air that is blown out of the hive by the ventilating process. Now, although it may be true that the bees do evaporate a large amount of water from their nectar by the process you mention, I can not think it is *all* done in that way, because the sheets of new honey, nearly ready to cap, oftentimes look like the surface of a liquid, only the contents of each cell present a convex shape, so as to look like a lot of beads laid in a tray. Arranging the honey in this way offers such a facility for rapid evaporation that I can not but think that this is a part of the process, and I can not see how they can operate in the same way where the cells are too deep. In old box hives we sometimes find cells two inches deep or more. I think it is pretty certain that such combs are not profitable; for if, during a great flow of honey, comb of two inches should be filled with raw nectar, what an amount of labor it would be to evaporate it, no matter which way the bees did it, compared with sheets of ordinary worker comb! The old honey you speak of, found in old box hives, I have always supposed owed this fine quality to its age, while the honey in new combs or shallow combs is almost always of the previous season's storing. Had you attended the conventions where this matter of partly filled sections was discussed, friend D., I hardly think you would be so severe on those who have had an experience different from your own. Old veterans, who sell honey by the ton, even such men as friend Elwood, said, if I am correct, they were obliged to call all honey second grade that was made from sections partly filled out the year previous. Of course, a good deal depends on how much difference between first and second grade in price. Now, I think the best way to get at the truth of this matter, especially as it is one in which doctors disagree, is to get as many testimonies as we can in the shape of reports from those who have experimented carefully. There are several reports in this issue. I am sorry to say that a good many of them have not

tried *both* ways, and at the same time been careful to use a few partly filled sections in every hive by way of a decoy, to induce the bees, especially *Italians*, to go above and store promptly. See the report of C. B. Jackson, in this issue.

W. Z. HUTCHINSON

AS AN EARLY GLEANINGS CONTRIBUTOR.

IN GLEANINGS for Dec. 15, among other biographical sketches was that of the subject as above. The portrait was a wood-engraving. Since that time, friend Hutchinson has had one of those Ives reproductions made from a recent photograph, for his own paper. As this is much superior to the wood-engraving found in our biographical sketches, we take pleasure in reproducing it here.

*As ever yours,
W. Z. Hutchinson.*

Friend Hutchinson began to write for GLEANINGS a few years after it started, and as he grew up, so to speak, with this journal, we feel more than an ordinary interest in him, and a few additional facts concerning his career as a writer on apicultural subjects will perhaps be of interest. The first item from our friend which appeared in GLEANINGS print will be found on page 247 of the volume for 1877. This was only a short note expressing his pleasure over an extractor we sent him. The next we see of him in print—at least in the pages of GLEANINGS—is in our issue for Jan. 1st, 1878. At this time he began a series of articles full of his “experiences.” These were

so valuable to the general bee-world that we decided to make them the leading articles of the subsequent issues. His intense personality shines from every one of these letters. Beginning in bee-keeping early in 1877, with four colonies, we find he made his bees pay for all such improvements as the growth of the apiary seemed to necessitate. As he was paying for a home, he had no money to spend on "improvements." Most of the necessary fixtures, he contrived somehow to manufacture for himself. All this he described in his early articles. To illustrate how he worked with his bees, and how he economized, we copy from one of these early papers, found on page 391, of 1878. After one year of real experience with bees, he says at the close of an article:

A SORT OF "HOME" PAPER.

I am a young man who has just bought and partly paid for a small farm. We, wife and I, are working hard to finish paying for our home; and we sometimes have to "figure pretty close," in order to obtain my "bee fixings." For instance, I had long wished for the back volumes of GLEANINGS, but had never seemed to have the money to spare to buy them; at last, however, by going into partnership with a neighbor, and earning my half by getting up a club, they were obtained.

In spite of financial difficulties, under which I commenced bee-keeping, I have prospered in it exceedingly well; perhaps my love for the business has had something to do with my success. I sometimes wonder if I do not think too much of my bees. For instance, I wore a suit of clothes last spring until I was ashamed of them, in order to save money to buy a swarm with an imported queen. What do you think, Novice? Do you think it is possible for a bee-keeper to be too devoted to his business?

And there is one thing more that I would like to ask Novice, and that is, don't you think it is a good thing for some of us enthusiastic young bee-keepers, that we—well, haven't any bank account? If we had, we would probably buy a whole lot of bees, all the "modern improvements," and then—why, then go into "Blasted Hopes," to be sure.

There, my first year's "experience" is finished, and if it has helped any one else in their "first year's experience," it has "fulfilled its mission."

These articles continued to be the leaders until 82 consecutive numbers were issued, ending Dec. 1, 1886, with perhaps two exceptions toward the close of that year. From this time on, his name occurs only occasionally, and finally dropped out altogether. During this time he wrote more or less for the *American Bee Journal*, *American Agriculturist*, and the *Country Gentleman*. Jan. 1, 1888, he started a bee-journal for himself, entitled the *Bee-Keepers' Review*. It is hardly necessary to explain the features of the *Review*, as most of our readers, if not all, have been acquainted through our advertising columns.

GOLDEN COREOPSIS, OR SPANISH NEEDLE.

63½ LBS. OF THIS HONEY AS THE PRODUCT OF ONE COLONY IN 6 DAYS, AND 202½ LBS. FROM 43 COLONIES IN 10 DAYS.

THE above name is now to be seen on many labels that adorn my buckets which contain honey gathered from coreopsis, or Spanish needle. I have added the word "golden" to embellish the name, as it were, and to give it a better send-off. Do you not think the name appropriate?

Something over a year ago I wrote a letter for

GLEANINGS, claiming that the honey gathered from this plant is superior to that produced from other fall flowers, and that it should rank among the very best grades, and command the same price in the markets as clover and linden honey. My peculiar location has, fortunately, placed me in a position to pretty thoroughly understand the nature of this plant, and the quality of the honey it produces. Located at the foot of the bluffs of the Illinois River, there is a broad expanse of low marshy lands to the east and south, from three to five miles in width. These lands are subject to overflows from the river once a year, which usually take place in early spring. This renders a large portion of the soil unfit for tilling purposes; and the consequence is, the Spanish needle has secured a permanent foothold, almost to the exclusion of all other plants; and early in September they begin to open their beautiful petals, and in a short time whole districts are aglow, and their dazzling brilliancy reminds one of burnished sheets of gold. It is now, should the weather prove favorable, that the bees revel in their glory, and the honey comes *piling in*; and the beauty about this kind of honey is, it needs but little "boiling down," and the bees no sooner fill their cells than they are cured and ready to seal. This is one great advantage, and saves the bees lots of labor, and makes the storage of honey more rapid. I had one colony of bees that stored 63½ lbs. of honey in six days; another one, 86 lbs. in nine days, and 43 producing colonies netted me 202½ lbs. in ten days—an average of 47 lbs. to the colony. This honey, though not quite as clear as clover or linden, is of a golden hue, exquisite flavor, and very fine body, weighing fully 12 lbs. to the gallon, and, as previously stated, I can not see why it should not rank in grade and price on the market with clover and linden honey.

So far as my market is concerned, there is no honey so universally liked by the consumers as my "golden coreopsis"; in fact, not one word of complaint has ever come back to me from this honey, save one. A neighbor ceased buying it; and when questioned as to why, he stated, "My children eat it up too fast." I am now running a peddling-wagon, and my salesman states he can sell more honey going over territory he has previously canvassed than to hunt up new routes. This certainly speaks well for this kind of honey. I have sold over 4000 lbs. in my home market this season, and the demand seems to be on the increase; and I believe if apiarists will locate their bees so as to get the benefit of these large areas of coreopsis they will not only be conferring a boon on their fellow-man, but will reap a financial reward for themselves. Another word in favor of the coreopsis honey: It is less inclined to granulate; and at this date there is but little sign of granulation, while my two barrels of linden honey is as hard as New Orleans sugar.

J. M. HAMBAUGH.

Spring, Brown Co., Ill., Jan. 21, 1889.

I believe you are about right, friend H., in regard to the Spanish-needle honey, although with us it does not go off like basswood and clover. I do not suppose that anybody will think of planting Spanish needle, but we can certainly do as you say—move our bees to great swamps and marshes, where may be found acres upon acres so full of bloom as to make it appear as if the ground were covered with snow, said snow

being of a bright yellow instead of white. In traveling on the cars I have frequently witnessed these great masses of bloom, and at times it fired me with enthusiasm to get some bees and set them close on the margin of these swampy wastes. I did it once at the foot of a lake near us. The bloom was not as full as you have described, but the bees built comb and stored honey right away, when those that were left at home were consuming stores and doing nothing. Now, then, who knows where there is a big patch of Spanish needle? and will you make preparations to move your bees near it, when the time of bloom comes?

HUMBUGS AND SWINDLES

PERTAINING TO BEE CULTURE.

THE old artificial-honey dodge has come up again; but as the author does not put any date on his circular, we can't tell whether it is old or new. The circular commences: "A work of ten years just completed! A fortune for you—will you take it? World's wonders; or, how to obtain riches!" There are thirty or forty secrets advertised for getting rich. The only one which concerns us principally, however, is the following:

ARTIFICIAL HONEY.—Equal to bees' honey, and often mistaken by the best judges to be genuine. It is palatable and luxurious; costs 8 cents a pound to make, and will sell for 16 cents per pound, while the bees' honey sells from 25 to 35 cents. Agents make money fast by selling the recipe to boarding houses, stores, and private families at \$1.00 each. In average territory you can easily sell ten recipes a day for \$1.00 each, \$10 clear profit. One agent writes: "I average a recipe at every sixth house."

"Luxurious," no doubt, and costs only 8 cents a pound to make. It happens, however, that *good honey* has been sold in considerable quantities until quite recently at 8 cents per pound; but bees' honey does not sell, nor has it sold for from 25 to 35 cents a pound, for years. The swindling sheet referred to contains on one side in big letters, the address of L. W. Lincoln & Co., 89 Aberdeen St., Chicago. I hardly need tell our readers that this is only a rehash that has cropped out every now and then for at least 30 years. When I was in my teens I sent a dollar in answer to a similar advertisement, and obtained a recipe for making artificial honey, and another one for silver plating, and something else thrown in. All such offers of valuable recipes for a certain sum of money we may safely pronounce humbugs and swindles. All recipes of any value may be obtained in our recipe-books; and a dollar nowadays pays for a pretty good-sized recipe-book. L. W. Lincoln & Co., aside from offering recipes, offer to sell their agents county rights at the very low price of only a dollar for a county. What *right* have they to give *rights* to certain counties, pray tell? A search through Dun & Co. fails to find any L. W. Lincoln & Co. in Chicago at all. No doubt, however, somebody is on the watch for the dollars when they come in for the secrets or county rights.

FALSE STATEMENTS IN REGARD TO THE HONEY BUSINESS OF OUR COUNTRY.

As a protection to our bee-keeping population, we propose in this department to publish the names of newspapers that persist in publishing false statements in regard to the purity of honey which we as bee-keepers put on the market.

PERMIT me to call your attention to the inclosed article, which I clip from an Eastern paper.

E. H. BARTLETT.

Mt. Vernon, O., Jan. 3.

I will explain to our readers that we wrote to friend B. at once, to give us the name of the Eastern paper containing the clipping. As he has not done it, or, at least, we have not received it at the present writing, Feb. 18, we give the clipping below:

BOGUS HONEY.

During the year 1865, or thereabout, I was walking on the streets in Baltimore, Md., and my attention was called to what appeared to be a beautiful specimen of Vermont honey, packed in boxes, and of the most beautiful clear liquid in the cells of white-looking comb. It attracted the attention of every one at the time, as the nicest honey that had ever been in Baltimore. But some time afterward it fell into the hands of an analytical chemist, who found out that the comb was made of paraffine, and the liquid of glucose syrup (made out of corn starch). The paraffine was made in imitation of the honey-comb, by some mode of pressure, by models prepared for the purpose, and the liquid glucose syrup had been made to fill the cells. Paraffine is now prepared from the refuse products of petroleum, when it is being refined, and the market is controlled, absolutely, by the "Standard Oil Trust," who can well afford to let it go on the "free list," as there is much more made in this country than anywhere else. This substance is like the most beautiful white wax, and makes candles like the purest spermaceti. I commend it to the attention of the committee having in charge the matter of "adulteration of food," etc., as I believe the ingenuity, sharpness, and invention, quite equal, if not superior, to that presented in the wooden nutmeg and the maple hams made in Connecticut.

Respectfully,

PAUL PRY.

I suppose I hardly need tell our readers that we are prepared to pay "Paul Pry", or any other man who will show us the above-described operation going on, \$1000. The whole story about the analytical chemist is false from beginning to end; and if any of our readers can help us to hunt up the author of these falsehoods, we will hold him up to the gaze of every man; and we ask every friend who has seen the above in any paper, to carry or send the editor a copy of this issue of GLEANINGS. We will furnish you as many numbers as you want. If the editor who has given place to the above will not recant, we want the privilege of holding him up to the gaze of every truth-loving man or woman.

Here is another:

Here is another crank. What shall we do to stop this nonsense? There ought to be a law to protect bee-keepers.

M. S. ROOP.

Council Bluffs, Iowa, Feb. 11, 1889.

A NEW SWINDLE.

The *Democrat* says a new swindle is said to have been discovered at Oskaloosa, by a woman coming in a drug-store and buying a half-ounce of "attar of roses"—a butyraceous oil of delicious fragrance, which separates itself from the rose-water during the distillation of dried petals of roses. A reporter heard this order, and his curiosity became strong as to why she should want so much of this expensive oil—retailing at from \$10 to \$15 an ounce. After much investigation he found that she used it in

the manufacture of "pure" honey. Syrup made of the proper consistency and color—an easy undertaking—with enough of this oil added to give it flavor, an article in all appearance, smell, and taste, so closely representing honey as to fool the most expert, and thus at a cost not to exceed 3 or 4 cents per pound to the manufacturer, this bogus honey is sold in this market as straight, pure strained honey.

Now, friend R., why didn't you tell us what paper you found the clipping in? We gather from the reading on the other side that it is a temperance paper, and the temperance paper seems to indicate that some Democratic paper first started the lie. I hope all good Democrats will help us to hunt up and straighten out our Democratic brethren. It is pretty clearly evident that some wicked sinner in the shape of a reporter is writing these things up; and the publishers of the papers he sends them to are foolish enough to believe them, and perhaps pay him for his sensational scares. Another thing, this statement is a slur on the character of all womankind. Think of a woman buying attar of roses to humbug the public! Then, again, the statement shows falsehood on the face of it. The idea that attar of roses, added to syrup of the proper consistency, should make it smell and taste so like honey as to "fool" an expert! No doubt there were fools around about that time, but I am sure it was not one of the fair sex, nor was it the general public at large that were fooled or humbugged by any such mixture. Now, friend R., may we trouble you to take this, or to send it to the editors of the paper from which you made the clipping, or the Democratic paper that first published it? Let us trace them back to the fountain-head, and get at the seat of the mischief if we can.

CARRYING BEES INTO THE CELLAR.

S. I. FREEBORN'S METHOD.

WE think we have a simple device for carrying bees into the cellar that will rather surpass friend Miller's rope. It is what we call a hand-barrow, made of two boards about 6 ft. long and 1 ft. wide, worked down to handles at each end, of the right size to be convenient to take hold of with the hand, some-

thing like this. To these we nail cross-pieces, making our barrow of a convenient width to set the hives on crosswise. This will hold three hives, but the number can be gauged by the weight of the hives and the strength of those carrying them. Some of the advantages of this kind of a barrow are, that, having the weight on the hands and arms, enables one to humor the motion, and prevent sudden jars that we could not prevent with the hive held firmly against the body, as we have to where we carry a hive alone. Its advantages over the wheelbarrow are, that it jars less, and you can get in and out of places that you could not with the wheelbarrow, and that, in the event of bees crawling out, they are not so apt to annoy us by crawling up our sleeves and other places where we do

not want them; and, also, we can keep the hives level while taking them in. This is quite a consideration when recently fed, as the added frames would likely be loose.

We noticed here the same thing that our friend Miller did at his place—that the bees did not frequent the grapes the past season nearly as much as usual. We think one reason for this lies in the fact that it was a very dry year, and fine for grapes. The weather was so favorable that very few cracked or burst their skins. May was a very cold month, and no doubt killed off a large per cent of the queens, or mother-wasps, making that insect very scarce, to the benefit of the grape crop. The little round holes spoken of, made with such regularity in the grapes, we have lately attributed to a little brown sparrow. We have not seen them in the act, but have frequently frightened them from the vines. On examination we found grapes freshly punctured. It seems to have been done by something with quite a long bill, and strength to use it.

Ithaca, Richland Co., Wis.

S. I. FREEBORN.

MY VISIT TO CALIFORNIA, AND SOME OF MY MISTAKES.

A. I. ROOT TAKEN TO TASK BY HIS FRIENDS.

M. R. ROOT:—You owe a big apology to the bee-men of Santa Barbara. After I and others gave you an invitation to come here you sent a note accepting our invitation. I put right into the city, saw two of the prominent men in the business, told them to work the thing up for your reception, spoke to one of the aldermen to take you by the hand, and show you around the city, to see our fine public buildings, water and electric works, etc. I went home, filled our larder with the good things of this life, hired an invalid (for I was busy) for one month to see that the cart and buggy were well oiled, and the horses well fed, so that, at a moment's notice, you could be run out to any point of interest; kept the best room in the house tidied up, and even the organ tuned up, all for your reception, and only to come to Ventura, and then turn back, when one hour's ride (4 bits) and an apology would have been satisfactory. My reason for not writing sooner is, I was so mad I was afraid I might say something unbecoming. I could not bear the looks of the paper, as it would bring the thing up to my mind so vividly.

J. N. GILCHRIST.

El Montecito, Santa Barbara Co., Cal., Feb. 24, '89.

Now, old friend, I am about as mad as a bee-man ever gets, I guess. You have been to California, and did not come to see me. Well, did I ever! I sat up two nights, and slept three days with my boots on, expecting you to come, but you did not. But I am glad you had a good time, and returned safe home to your family and business.

Dehesa, San Diego Co., Cal.

A. W. OSBURN.

Dear friends, if it would do any good I would sit down and have a good cry over my blunder in not meeting either of you. You see, I had no comprehension of what an awful big country California is. Besides, when I started away I was a good deal disturbed and perhaps somewhat excited. I

took along quite a number of letters, and fully intended to take both of yours. After I started I did remember your kind invitation, and my promise to call on you; but I knew so little of the names of the places that I could not remember very much about it. When I stated the matter to friend Wilkin he said you would doubtless all be at the bee-keepers' picnic he had planned, and that he sent invitations through the beemen in the vicinity. Well, you were not at the picnic, and I had made arrangements so that my allotted time was up and more too; and before I knew it the time had gone by. Mr. J. S. Harbison did tell me, the night before I left San Diego, that I could not very well go without seeing Mr. Osburn; but arrangements were then made so that it was next to impossible; and friend Wilkin did tell me that I surely ought to visit Santa Barbara before I went home. Please forgive your old friend for his awkwardness this time, especially when he tells you that he is now planning another and longer visit, and this time Mrs. Root is going. She is pretty sure she can not follow over all the mountains, but possibly we can leave her to visit with some of the women-folks while we do the climbing. Won't this do, friends G. and O.? Please don't feel mad any more.

CELLAR WINTERING.

LOSING BEES IN LOCATING ON NEW STANDS.

THERE is one thing that has always been a wonder to me in my experience in keeping bees; that is, how they are carried around and piled up in cellars, like so many potato-barrels; carried out again some warm day for a fly, then packed back again in the evening and ricked up, and not one word about losing bees in all the years I have been reading bee-papers. My experience since I have been in the business is, that if I pick a hive up and carry it to a new location—no difference if it is from 4 ft. to 300, quantities of bees will go back and cluster around in lit, the bunches, apparently lost entirely. Night coming on, I have often, out of pure sorrow for the little fellows, put back the hive in its place, to see them apparently made happy. Now, is that unnecessary sympathy in me? This may be very unimportant, as there seems to be so little said on this point; but I tell you, it is something to me. I have invariably, in moving my hives, had to move them little at a time, and tole them, as it were, till I got them where I wanted them. Is that unnecessary? I used to think instinct taught them to follow their queen; but I've learned better.

Now, the case in point is just this: I had two hives set off by themselves (for convenience and room), say about 3 rods. I moved them back to the main apiary in November, to pack for winter. They had not had a fly for about five weeks, which proved to be rather chilly in the evening. I was not at home; but when I came, my wife asked me what the matter was with my bees—they had been swarming around that new place till dark, and great piles of them were clustering on the fence and shed. The night was cold and windy, with some rain. I looked after them as soon as I could see, to find what hadn't blown away of them; but

bunches and piles were huddled together dead, on posts, fence, roof, and everywhere. Now, am I to expect such losses, and let those that hadn't sense enough to go home out of the rain take the consequences of their own folly, and think nothing about it? or am I to blame myself for part of it?

If this is not important enough to notice in GLEANINGS, a word from you will suffice; but I want light on the above subject.

By the way, friend Root, I am an old Californian, having crossed the Great American Plains in 1852. I should really like to have a good talk with you about experiences; but I am rather surprised at a man of your cloth, at this late day, lying out in barns and sheds at night with strangers, even sleeping with them—deaf ones at that. I have been put to the necessity of slipping off by myself to the mountains, and building me a fire to keep off grizzlies, to put in a night when I couldn't do better; but I wouldn't have trusted any strange man, for fear he would have killed me for my boots. At some future time I should like to compare notes with you, if you like. Let me hear from you.

S. DANIELS.

Pine Grove, O., Feb. 7, 1889.

Friend D., if you will turn to page 81 of our issue for Feb. 1 you will see that our experience is just about like yours. I do not believe in moving bees, any more than you do, and that is one reason why I made the chaff hive to be a permanent home for each colony. When I want to move a colony, one that is in a chaff hive, I take as many combs and bees as I want, and start a nucleus in that chaff hive with the bees that returned to their homes—that is, where I want to move bees short distances. —You must have forgotten that I said the man I stayed with in the barn got out his old well-thumbed family Bible, and read a chapter before we went to bed. You see, that made us not only well acquainted, but brothers, and so I was not "away off among strangers" at all.

THE NAMELESS BEE-DISEASE.

A MALADY WHICH IS WORKING HAVOC IN A CALIFORNIA APIARY.

FRIEND ROOT:—I am somewhat in the frame of mind the man in the A B C was whose hopes were blasted, and thinks of emigrating. Some of our bee-men here wish me to state the case, as they are somewhat anxious.

Last September I began to notice that my bees were dying, a whole swarm going at once, seemingly. It was toward the last of my run of honey, and pretty hot weather. In the course of a month, 10 or 12 swarms had gone, some of which were full of honey at the last extracting. In December some 50 more died, and at this writing another hundred is added to the list of dead. The brood-combs, as a general thing, are left clean of brood, with the exception of some dead at the advanced stage of growth, where the bees had begun to gnaw out, or have the head out. The mature bees seem to have what you term dysentery, voiding the yellow excrement. The abdomen is distended, and sometimes filled with white or almost transparent fluid. The bees fall in a pile at the bottom of the hive; in fact, your description fills the bill, except as to the con-

dition of the weather. The past month, when the decline was so rapid, the weather was cold and foggy much of the time. Some swarms, which have pulled through to the present, with a handful of bees, are now raising some healthy brood, only a little, of course. As I remarked at the time the bees began to drop off, the crop of honey ceased to come in, except in a few colonies which continued to work later, and up to the time that other apiaries suspended. I note what you say about aphides, and would remark that honey-dew is secreted at the season of which I write. The swarms which pulled through so far are those which worked the longest, and evidently obtained their stores from other sources. Now that the weather is warm, these are robbing from deserted hives, and putting it in the brood-nest; and that, added to the fact that a few combs placed in another apiary to feed upon do not seem to have any bad effect, is still more of a puzzler.

So far as I am able to learn, the trouble is local. Others are not losing any more than the usual percent. Whether this is the opening of some pest on the honey crop, or whether it is a special or local cause, remains to be seen. I have feared that it might be in connection with my water supply. Ditch water failing, I resorted to tubs made from barrels in which I tried to make vinegar; but owing to inexperience I made it too strong of honey, consequently obtained only a worthless alcoholic slop. These were, of course, washed out and frequently filled, and were in use about two months or more. It was after the removal of running water and dew that the greatest fatality commenced. You will notice that it did not affect all simultaneously, but skipped here and there. My hives are set directly upon the ground, as do many in this community. I shall make an effort to build up again, and should like to use these combs. Do you think it safe?

Bee-men here feel that you made a mistake in passing by Kern Co. Although we are not so noted as our southern neighbors, nor as good and virtuous, yet we have taken the first premium for three successive years at the State Fair, and have several thousand stands of bees. If you had called you would have seen things equal to motor roads and Sweet Water Dam, though of a little different nature, and probably "sold the boys something to-day." Our own personal trade will, under the circumstances, be small; but our neighbors exported something like 150,000 lbs. of comb honey last season. One of them told me he had ordered \$1000 worth of supplies already.

I should be glad of your opinion on the problem I present, as my experience is limited, and this misfortune comes at a time when it falls exceedingly heavy.

W. A. WEBSTER.

Bakersfield, Cal., Feb. 4, 1889.

Friend W., taking all things into consideration I am inclined to think your bees were killed by drinking the water in those tubs. You may remember that my carp were killed by putting them over night in a barrel that had been used for pickles. The barrel was washed and rinsed, but there was vinegar enough in the wood to contaminate the water. When I first commenced reading I decided that your bees had got hold of some poison—probably the effects of Paris green or London purple, used for killing insects in your vicinity. I would put

the water for bees in shallow stone crocks. Throw in clean pebbles or gravel to keep them from drowning. Perhaps you will soon have irrigation in your neighborhood, and that will fix the whole matter.—Yes, I made a good many mistakes in not visiting different locations and calling on all those good friends of mine. See what is said about it in another column.

HYBRID HELLEBORE, OR CHRISTMAS ROSE.

SOMETHING TO GLADDEN THE BEES AND TO GLADDEN YOUR DOORYARD.

WE extract from *L'Apiculteur*, of Paris, the following article, which we believe will be of interest to our readers, for whose benefit it is translated from the French by our proof-reader, Mr. W. P. Root.

Here is a modest plant, the blossoms of which are the first to make glad the bees when they make their first excursion from the hive during sunshiny spells. They get pollen from it in abundance. For this reason the Christmas rose should have a place in every bee-keeper's garden. It is very rustic in other respects, and is quite indifferent as to the nature of the soil. It is propagated either from the

VILMORIN'S CHRISTMAS ROSE.

root or from the seed. Whole basketfuls of hellebore may be found near clumps of trees. The regular leaf of this plant, of a dark green, issuing from the peduncle, constitutes a summer ornament. At the country residence of Ricquebourg, near Resson, Oise, France, the cultivation of Christmas roses in hot-houses requires a space of from 100 to 150 square meters. Every week during winter, the flowers are cut off and sent to Paris for the decoration of rooms. Hellebore, or Christmas rose, begins to blossom near Christmas, from which fact it derives its name, and continues through January and February, and even into March, depending on the rigor of the winter.

A small packet of seed, weighing 10 grammes, is sent free by the house of Vilmorin-Andrieux, 4 Quai de la Mégisserie, Paris, France, on receipt of 11 cts. to pay for packing. As the above firm solicits orders from America, I presume they are prepared to receive our postage-stamps; also to read communications in our language.

BEE-KEEPING IN SOUTH AFRICA.

CHAPTER II. OF A MISSIONARY'S EXPERIENCE IN STARTING IN BEE-KEEPING.

DEAR GLEANINGS:—In my first letter, published Dec. 15, I promised to send Chapter II. of my experience when I found time to write it; and that seems to be the present time. I told you that I had three boxes of bees (I do not feel justified in calling them hives) as the result of my capture of about three times that number of colonies of wild bees. Then I sent to America for "a good book on bee-keeping"—Langstroth's. I knew that bees were in the habit of sending off swarms; but these of mine, if they had ever swarmed, did it when no one was about. It was not possible for me to keep watch of them, and how was I then to increase the number of colonies? I read what was said about "artificial swarming." Ah! there is the solution of the difficulty. I determined that I would divide my three colonies and make them into six, and another year the six would become twelve, and a third year—but I will go no further. I believe I was to be contented with ten good colonies. Mr. Langstroth's directions for artificial swarming are very specific, but there were difficulties for which he had not provided. For one thing, our seasons are "the other end to." He talks about swarms in May; but that is when our winter begins. That is all the winter we have, if it is proper to speak of a winter where there is not even a frost. Then, again, he speaks of certain plants being in bloom, as the white clover, the basswood, etc., none of which we have. Of course, we have honey-plants, and, of course, bees swarm, and swarm when there is honey to be gathered; but what are the honey-plants of Natal, when are they in blossom, and when do bees swarm in a country so warm the year round that there is no frost? I did not think so much of these various conditions then as I did after I had tried artificial swarming. The directions were so plain that I felt sure I could succeed. Mr. Langstroth gives fair warning of the danger of failure, and of the need of going slow. But as people so often, when they hear a good sermon, give it to their neighbors, so I considered that these warnings were for those who did not follow the directions carefully.

I had about a dozen hives with movable frames made in the Industrial department of the school. This department had only just started, and the boys in the shop did not yet know much about using tools. I must also confess that it was my own fault that I did not get better hives. I did not think I could afford expensive hives, and so attempted to have some paraffin-cases made over into hives. Kerosene oil is called "paraffin," in Natal, and comes to us in tins protected by wooden cases. These cases, when laid on the side, are about the size and shape of an L. hive; but although they were cheap, it was a penny-wise and pound-foolish plan, as cheap investments so often are. The trouble was not that the hives retained the smell of the kerosene, but there were cracks and knots in them, and in time the cracks became wider and the knots came out. To make matters worse, I tried to make them into observing-hives, with a glass and a door at the back. I can see now how foolish it was; but that did not help any then. As some one has said, "If only our foresight were as good as our hindsight, how wise we should be!"

My hives were made and painted in our winter, so when spring came I was ready to multiply my three colonies into six. Formerly I had carried on my operations with bees at night; but now acting on a suggestion of Langstroth's, that whoever attempted to do any thing with bees at night was sure to repent of it, I determined to try the day for transferring and dividing my bees. I had made a bee-hat by framing a small glass and sewing it into a strip of mosquito-netting. Like many others in this country, we had the idea that mosquitoes abounded everywhere in Africa, and took out with us a large roll of mosquito-netting, which we never had occasion to use. My bee-hat was not a success. The moisture from the breath, condensing on the glass, made it little better than a piece of tin to look through, and the frame bumped against my nose and face rather disagreeably. I had bought a pair of weeding-gloves, which answered very well for bee-gloves. I see friend Root does not approve of handling bees with gloves; and I will confess that, when I saw the gloves covered with stings, and thought that every sting meant a dead bee, I felt very sorry for the bees; but my sorrow was tempered with thankfulness that the stings were in the gloves and not in my hands.

The day selected for operations was bright and hot, and the time about noon. Armed *cap-a-pie* we sallied forth; that is, I was armed; but the native boy who was to assist me was not. My unpainted boxes had become somewhat rotten by this time, and the bees had found numerous places of exit besides the one I had made for them. It was not an easy task to carry out the direction of the book—to close the entrance of the hive and remove it to another place while transferring. I might close one entrance, and the bees would rush out from half a dozen others. However, I thought I could manage it. My plan was to throw a sheet over the hive, lift it quickly from the ground while the boy grasped the ends of the sheet underneath the hive and twisted them together, and thus confined the bees. The plan worked beautifully until a stray bee made straight for that boy's eye, causing him to drop the sheet and run. Strange as it may seem, those bees were in a decidedly bad temper as they rushed forth to see what it all meant. I thought my armor was bee-proof, but soon found out my mistake, and ran to find out where my boy had gone to. The spectators all laughed, and this suggests a puzzle which might be offered by some enterprising paper as a prize puzzle. There is no copyright on it. Puzzle: What is it that is so funny in seeing other people stung? I do not ask this reproachfully. I have myself been in both places, and I laughed when I was a spectator, and didn't laugh when I was in the other place. At that particular time I was in the other place, and did not feel like laughing. I began to think the day was no better than the night for handling bees, and that Langstroth might have said, "Night or day, you will be sure to repent of it."

It will probably be thought that, under the circumstances, we postponed further operations to another day. Very likely that would have been the part of wisdom; but wisdom was an article we had not yet acquired so far as bees were concerned. I afterward learned that the principal object of bee-keeping was to acquire bee-wisdom. No; I did not wait till another day, but, readjusting my armor, I went back and tried again, and finally drum-

med the bees into a state of acquiescence to the inevitable. The comb was transferred to frames, and the bees were divided into two colonies. Previous to this we had moved out of the "bee-haunted" house into another not far away. I had there prepared a nice shady place for my ten colonies of bees which I was to obtain by artificial swarming. I had not then seen friend Root's plan of placing the hives on bricks, and filling up to the edge of the hive with sand. How the white ants would like that! They would come up through the sand and eat their way through bottom, sides, and top of the hives, leaving only a shell where there was a solid board. I had prepared a place by thinning out a clump of bush, and driving down posts of a native wood, a species of olive, so hard that even the white ants do not eat it. On these posts I nailed boards, and here placed the hives. It was a beautiful place, and it would seem as though any right-minded bees would settle down at once to good honest work, on finding themselves in such a home.

I fear that my bees were not right-minded; for the results did not justify the confidence that I had placed in them. I transferred and divided my other two colonies, or, rather, one of them, I should say; for as I was about to proceed against the other I found that they had just sent out a swarm which was waiting for me on a tree close by. I left the parent colony in their old box, and hived the swarm, removing both to my new apiary. So I now had six colonies, and I became ambitious to get ten. So I told the boys that, if they would find some colonies of wild bees, I would give them a sixpence for each one pointed out. I had some qualms of conscience at the time for offering so little, and some regrets afterward that I had given so much. I completed my ten colonies with rejoicings. Another year I would feast upon honey, I thought. But it is well not to count chickens before they are hatched, and not to eat honey before it is gathered. In another letter I will tell you what became of my ten colonies of bees.

H. D. GOODENOUGH.

Clifton Springs, N. Y., Jan. 23, 1889.

Friend G., you kept me uneasy during all your description, because I did not find anywhere that you spoke of using smoke. Why in the world did you attempt to do anything with bees until you first had given them a good smoking, according to the books? Even if one could fix himself up with gloves and veil, and every thing else that has been used, to make a regular bee-proof armor, I would by no means think of handling bees without smoking them. They will be pretty sure to find a break in the armor, and get through. Even if they should not, you will get them so furious as to attack passers-by and domestic animals; and I do not think that anybody has any right to arouse a colony of bees to such a fury as trying to handle them without smoke does; and this is one great reason why I object to gloves or veil either; better lose the time required to bring the bees into perfect subjection than to have them on the wing stinging right and left. When we throw away our veil and gloves, and carefully learn to judge by their behavior as to what bees will do, we soon learn to handle them with comparative impunity, even

when an inexperienced person would rouse them to fierceness; and we also learn the time of year and the time of day the bees can be handled safely and when they can not.

BEE-KEEPING IN UTAH.

FURTHER FACTS IN REGARD TO THE TERRITORY AS A HONEY-COUNTRY.

BEE-KEEPING in Utah, as far as I have been able to judge, differs but little from bee-keeping elsewhere. The hives and fixtures are about the same, while the pasturage seems to be more sure than in most places.

We almost always get some surplus, and it is generally through extracting too close that we have to feed. Of course, the crop varies with the season. If we have a dry season, and sweet clover is not so abundant, we have a light crop.

The hives used are of various patterns and dimensions. The Kidder predominates among the farmers and those not considered to be practical bee-keepers; while among good bee-keepers the Simplicity, Heddon, and what we call here the "Short Langstroth," or a frame that fits crosswise of a ten-frame Simplicity, is used.

The bees are a cross between the black and Italian, with a predominance of about two-thirds in favor of the latter, although we have had importations of other races at different times. Our best honey-gatherers are generally those that are considered a trifle cross.

Comb foundation plays a very prominent part here among practical bee-keepers.

The sources of honey are various, the most prominent of which, as I have before stated, being sweet clover, while the bees gather considerable from fruit-blossoms, alfalfa, wild flowers, etc. The surplus-honey flow does not generally commence until sweet-clover bloom, which begins about the first of July; and in most seasons it continues until the first of September, although the bees generally gather enough to live upon from the middle of April until late in October.

In a dry season we do not have to wait for the honey to get sealed, as it is pretty thick when gathered, therefore we can extract, generally, when the frames are full, which, in dry seasons, is about every ten days. In moist seasons which, by the way, are very rare, we have to let the honey get about a third capped. The honey taken in the above way candies in a very few weeks, and becomes very solid. It is then (with us) in a very good condition for shipping.

Comb honey is handled much in the same way as in other places. The T super seems to be, all things considered, the best adapted to our system of management.

In handling bees during the season, the minor points in management are as many (if not more) as the bee-keepers, while the main points are about as follows:

Along in March or April, according to the season, the hives get a thorough cleaning; all dead bees, dirt, broken combs, etc., are removed; the hives are straightened up, and the litter, etc., is raked up and carried away from around the hives; and if any bees are without stores, full frames from those that have plenty are given them.

In May, queen-rearing and dividing claim our attention. In June, the stocks are all built up, and every thing is put in readiness for the honey-flow; the supers are put on the last week in June or the first of July. In about two weeks extracting commences, and keeps up until the last of August, when the surplus-honey flow generally ceases. The supers are left on until about the first of October, to catch any surplus that might be stored, then they are taken off and the bees are packed for winter.

Bees are generally wintered in single-walled hives on summer stands, although chaff hives are used. Some give their bees considerable protection, while others consider it unnecessary.

The honey-market here is not the best in the world, as there are by far too many small producers; but I am happy to say that their ranks are weakening. Fruit-growers here look on bees as their friends, while the bee is considered the emblem of Utah. We hear very little about adulteration of honey, as it will not pay.

We have considerable trouble with foul brood, which is generally found in old tumble-down Kidder hives, but very seldom found in a well-kept apiary. In fact, I have never seen the disease, except in neglected apiaries. The foremost bee-keepers of Utah are young men, and you may hear of something from us in the way of bee-keeping, in the near future; but be that as it may, bee-keeping in Utah has come to stay, and I predict that, in a very few years, it will be quite a source of revenue to the Territory.

J. C. SWANER.

Salt Lake City, Utah, Jan. 24, 1889.

CARE OF COMB HONEY IN WINTER.

HOW MUCH DOES IT DETERIORATE IF PROPERLY CARED FOR?

A GREAT many honey-producers seem to act on the belief that honey is a perishable product, which must be placed on the market as soon as possible after it is secured. Just as soon as the honey is taken from the hives or at least as soon as cold weather is at hand, they make haste to ship it to commission merchants in some of the large cities, or to crowd it upon grocerymen of their own neighborhood, far beyond their immediate needs. Various evils result from this. In the first place, the markets are often so overcrowded that prices are forced down below where they really belong and would remain if more wisdom had been shown in disposing of the product. As it is, these impatient and over-hasty sellers often fix the price for the remainder of the season, causing loss not only to themselves but to others. The offenders in this direction are usually the small producers; but many large producers are not exempt from the same charge.

An objection that is perhaps more serious to this careless way of disposing of a season's labor is the fact that honey usually deteriorates very rapidly after it leaves the producer's hands. Comb honey may be kept from one season until the next, unimpaired in quality, but it requires some care and a proper place for keeping it. The producer ought to be able to supply these, while it is perhaps too much to expect of the dealer. The average commission store is a very poor place for storing comb honey, and many grocery stores are not much bet-

ter. It is almost needless to say to any honey-producer, that honey should always be kept in as dry a place as possible, because in a damp place it soon absorbs moisture, and becomes thin and watery. The surface of comb honey "sweats," or becomes covered with drops of moisture, and the nice white comb becomes dark and unattractive, owing to the increase in bulk of the honey in the cells. Sometimes the caps of the cells even burst from this cause, and frequently the honey undergoes a partial fermentation, and loses much of its sweetness. The honey in unsealed cells and broken places becomes so thin that it runs almost as readily as water when the comb is turned on its side, daubing every thing beneath.

All these results I have seen for myself. Once while making a tour of inspection among the commission houses of one of our large cities I came across a large lot of honey, the producer of which was known to me, and I knew that he had taken unusual pains that his honey might reach the commission merchant in the best condition possible. There it was, stored in a cellar which, with its damp, cold atmosphere, was of all places the most unsuited for the proper keeping of honey. At another place I found a large lot of honey in a room intended for the cold storage of butter and eggs. It was (or, rather, had been) an extra fine lot of honey, and the merchant was taking extra pains with it, as he supposed; but somehow, he said, it was not keeping well. No wonder. It was worth at least three cents a pound less than when it left the producer's hands. Some may see in this a reason why their honey sold for so much less than they expected.

This state of affair may perhaps be somewhat improved by a little missionary work among commission men; but the producer must expect to bear the brunt of it himself. In the first place, honey should be prepared for market by a thorough ripening. This is best done by storing the honey in a room which may be heated to about 100°, and kept at that temperature as long as desired. An oil-stove will be found an excellent arrangement for heating the honey-closet, or, if the closet is small and the weather not very severe, an ordinary large-sized lamp will answer. Neither of these will require attention more than once or twice a day.

This ripening process should begin as soon as all the honey is removed from the hives and stored away, and continue for several weeks. By this means the honey is thoroughly ripened, and acquires that rich pleasant taste so often remarked as belonging to honey which has been left in the hive for a long time. More than this, the honey in all unsealed and broken cells is evaporated down until it is so thick that it can not run from the cells. Any one who has ever handled leaky and dripping comb honey will appreciate the advantage of this. "Your honey is always so clean and dry—no stickiness about it," was the remark made to me not long ago by a dealer of considerable experience.

After the honey is once well-ripened it is scarcely necessary to keep the room at this high temperature, although it would no doubt be advantageous. Unless it is kept reasonably warm and dry all the while, it should be warmed up whenever the weather is very damp or very cold. If this is done, the honey will not attract moisture, nor crack, as often happens in very cold weather. If proper care is taken in regard to temperature and dryness, comb

honey may be kept in good condition for an indefinite time.

I hope I shall not be thought egotistical if I remind some who have written of this plan as if it were their own, that I was the first to recommend artificial heat for ripening comb honey. "Honor to whom honor is due." Surely, brethren, it does not cost much to give proper credit for an idea.

After you have your honey in good condition for the market, do not ship it off to commission men in large lots unless you are sure it will receive proper care until it is sold. Keep all who handle your honey, whether commission men or retail dealers, constantly supplied, but let their stock on hand be gauged as closely as possible by the running requirements of their trade. Any amount beyond this is safer in your own hands. J. A. GREEN.

Dayton, Ill., Jan. 30, 1889.

Friend G., I can attest to the truthfulness of every point you make. I have seen comb honey after it had been kept a year or two, and we have had some experience ourselves. I am pretty sure it will pay the owner to examine and fix up any honey that is held over a year or two on commission.

THE SILK-MOTHS OF AMERICA, ETC.

PROF. COOK DESCRIBES THEM.

MISS EVA M. WATROUS, Lake, Mich., sends in a *strong tin box* the cocoon of one of our largest silk-moths—*Lelea polyphemus*, or cocoon of the oak-tree silk-moth. She says, "We found it on a lilac, under an oak-tree. Mother thinks it comes from a long 'worm' which feeds on the oak."

Bless these mothers! They are usually correct. The lilac-bush grew close beside an oak-tree. The teacher, she says, said it was a tomato-worm. Bless the teachers! but, as this shows, they are not always correct. Miss Eva closes with, "Please oblige and instruct us, and perhaps many who are interested in nature's wonders, and who are readers of GLEANINGS."

This cocoon is more compact than is that of the silk-worm that feeds on apple, etc. It is dark gray, three inches long, and nearly half as wide. The dried-up larva is inside; but it would never have produced a moth, as parasites have devoured its substance. These little parasites, whose life-history I hope soon to give in GLEANINGS, are ever on the alert, and bring to naught many a large insect. Had our friend placed this cocoon in a close box, she would have reared some of these parasitic flies.

The oak silk-moth is one of our largest American silk-moths. They are buff in color. A heavy black stripe, bordered with a narrow white line, cuts off a strip of buff on the margins of the wings, which trims up the moth in fine style. A transparent eye-spot marks the front wings. This is bordered by a narrowing of white and black. A larger similar spot on the hind wings has a large blue patch inside of it. The beautiful green larva has deep red tubercles, which bear hairs.

These insects form an excellent silk, perhaps equal to the Chinese silk-worm. Indeed, a Boston gentleman had a plantation devoted to their culture a few years ago. Disease, however, got among them and cut short a very interesting ex-

periment. All of these large silk-worms, of which we have several species, spin their cocoons in the trees, attaching them to twigs. One of them, the *ailanthus* silk-worm, fastens to the large compound leaf. But this leaf falls, so some provision is necessary to keep the cocoon up in the tree where all is high and dry; hence the larva, before spinning its cocoon, goes to the base of the leaves and fastens them securely by silk threads which are firmly attached to twig and branch. Where this is not necessary, it is not done. Is such discrimination mere instinct? To call all such actions mere instinct is making instinct a greater thing than is reason. Instinct is only inherited habit.

A. J. COOK.

Agricultural College, Mich., Nov. 6, 1888.

DOOLITTLE'S CAVE.

WILL SUCH A CAVE ANSWER ON CLAY SOIL, WITHOUT SPECIAL PROTECTION?

FRIEND DOOLITTLE has persisted that bees can be wintered without any sub-ventilation, and without any attention whatever to ventilation. Now, if it can be done as easily and at as little expense as he says, there would be a good deal of saving of time and expense. His last article (p. 41), and the remarks under it, with the foot-notes on p. 46, and especially the fact of his success, make me have a good deal of hope that he may be all right. To me it would be a very delightful thought to think that I could put my bees away in the fall, without care, and with no anxious thought about them till spring.

To the last question in the foot-notes, "Would it do to shut up a cellar tight, in a damp clay soil?" I should very much like an answer, for that's just the soil I have. Most rose-cultivators approve of covering roses, before freezing, with soil. One year, just before freezing up, I covered my hardy roses with soil, and in the spring not more than five out of a hundred were alive. The soil was clay, and very wet at the time, and I think the roses were smothered. I suspect bees would smother if shut in the same soil. But if it be the covering overhead that allows the ventilation, as you suggest, friend Root, then the case is not so bad; for material could be hauled from some distance. Possibly some other material than soil might answer. I do not know that it is any thing strange that Doolittle's cave keeps "as low as from 43° to 46°." You say Mammoth Cave holds at 56°, summer and winter. I suppose Doolittle could find a depth at which he could hold, say, 54° summer and winter, the temperature outside ranging between the extremes of 30° below and perhaps 95° above. At a trifle less depth it would slowly vary from 53° in winter to something like 55° in summer, and at a still less depth the variation would be still more, until we reached a point where, instead of 54, summer and winter, we might have perhaps 9° lower than 54 in winter, and 9° higher in summer, only at this point we should have slight variations with the weather, making it in winter from 43 to 46 instead of staying uniformly at 45.

I don't know but I'll have to give under to Doolittle in this whole matter of wintering; but to save his chuckling over it, the printer needn't print this in the copy of GLEANINGS that is sent to Doolittle.

DILWORTH'S "EXCLUSIVE RIGHT OF TERRITORY."

More and more, as men think of making a regular business of raising honey this matter of exclusive territory "will not down," but will come to the front. For one, I shall gladly welcome any fair and honest solution of the problem. Friend Dilworth's plan is "to pay each farmer or lot-holder within the flight of his bees a certain sum yearly, not to keep any bees on his property." It is something after the plan recommended by Mr. S. T. Pettit, of Canada. In the foot-note, friend Root says, "Go to your neighbors all round about you, if you are located in the country, and get them to sign a paper, agreeing not to keep bees under a certain number of years." The plan has a look of fairness about it. Now, will friends Dilworth and Root put it in practice? If I am not mistaken, friend Root has said he would like to have exclusive territory; and if I am not still more mistaken, there isn't a man in the business, having as many as a hundred colonies, who would like another hundred colonies set down within half a mile of him. So, friend Root, you are just the one to try it. Still, I'm not so sure that I hate you bad enough to want you to try it. If you were to start out to-day to get every one within a mile of you to sign a paper not to raise oranges in the open air, I think it would cost some money; for people who never dreamed of raising oranges would feel sure there was money in it, and I'm not sure but it might be the means of getting some started in the business. So in the bee-matter, I think you would find a good many who would refuse to sign altogether, and others to ask an unreasonable sum, while the very fact of your attempting to buy some men off would start them to thinking whether they ought not to keep bees. Then suppose you have bought up or had given you all the territory within two miles of you, except just one acre that belongs to old Grasper, within a quarter of a mile of you, the whole affair is utterly worthless unless you can get that acre, and Grasper has you at his mercy. Then there may be sheriffs' sales, and things of that sort among so large a number, and then your previous arrangements are upset.

I have just looked at the map, and counted the different parties owning land on one-fourth of the ground within two miles of me—and surely apiaries should be at least two miles apart, if of full size—and I find there are 30. This includes no village or suburb; and if I take in the whole ground, village and all, it runs up into the hundreds. Excuse me from stirring up those hundreds. I have no trouble now, and never had; but if I started out with a paper I might make myself trouble. You can see, friend Root, that, in the great majority of cases, you would have from 100 to 500 parties of all sorts to deal with. But friend Dilworth is just that much ahead of the majority, that he sees *some* plan is needed.

C. C. MILLER.

Marengo, Ill.

I grant, doctor, that, in my locality, it would be a pretty big job to get exclusive territory; but where one has a farm, and all around him are large farmers, it seems to me there ought not to be any difficulty in purchasing it. Large farms do not change owners very often. If that does not answer, go where land is cheap, and buy all within a mile in every direction. Who will tell us how many acres it would take? By the

way, almost everybody in our neighborhood has given up bee-keeping, and I believe that that would be the result to a certain extent in the course of a number of years, especially if the acknowledged bee-keeper of the locality does not have any very big bonanza, and *they* do not come very often.

BEE CULTURE IN PREMIUM LIST.

WHY THIS INDUSTRY HAS NOT RECEIVED THE POSITION IT DESERVES.

I WISH to call the attention of our bee-keeping friends at large to a matter in which I think we are all interested; that is, the manner in which our vocation is neglected by agricultural societies. I find, in looking over a great many premium lists in this and adjoining States, that bee culture is recognized in only comparatively few of them. Now, why is it so, and who is at fault? Is it the officers of said societies, or bee-keepers themselves? I am inclined to think that, in a majority of such cases, it is the latter; for in my experience with agricultural societies I have never met a board of officers who were not only willing but anxious to add an apianian department to their premium list.

As I have intimated that bee-keepers are at fault, I must explain wherein. As a rule, officers of agricultural societies are not conversant with or skilled in apiculture, consequently are at a loss to know the requisites in an apianian department, which could be furnished them by almost any bee-keeper who would volunteer to do so. But this is too often neglected or deferred until too late; and the consequence is, apiculture is left out. Now, friends, let me insist that every bee-keeper consider himself a committee of one to look after this important matter of seeing that our industry is represented in your respective agricultural premium lists. In case you should meet any opposition in the board of officers, press upon them the fact that bee-keeping is an essential branch of agriculture, in that the honey-bee is indispensable to the fertilization necessary in the vegetable kingdom; that honey is a production of the farm, and can be had at the door of every farmer who will acquire the proper knowledge of handling a colony of bees. Besides, it is a wholesome and desirable article of food, and is getting to be one of the staple articles of our markets, therefore its production should be encouraged by every agricultural society in the land.

Now, friend Root, as some of our bee-keeping friends may be a little backward, and feel incompetent to furnish the requisite list, and as it has been suggested in GLEANINGS that a list be published as a guide for those interested, allow me, with your assistance, to submit the following form, or criterion, for county fairs:

	1st Pr.	2d Pr.
Best colony Italian bees.....	\$2.00	\$1.00
" " Native, or black bees....	2.00	1.00
" Italian queen-bee	1.00	50
" Display of comb honey, quality and manner of putting up for market to be considered.....	3.00	1.50
" Display of extracted or strained honey, for market.....	2.00	1.00
" 5 lbs. fancy comb honey.....	1.00	50
" 5 lbs. fancy extracted honey....	1.00	50
" Specimen comb foundation....	1.00	50
" 5 lbs. beeswax.....	1.00	50
" Bee-hive for all purposes.....	1.00	50
" Display of apianian implements	3.00	1.50

Benton, Ill., Feb. 12, 1889, WM. HUTCHISON,

Your ideas are tiptop, friend H. My experience has been exactly like your own. When the officers of our county fairs blunder, and make themselves a laughing-stock for all bee-keepers, it is the fault of the bee-keepers, because they did not come and help and properly post them. Perhaps the officers of some county fairs think they can not afford the amount of money (\$27.00) in your table; but in such an event, the bee-keepers should turn in and help. After you have once showed the officers what you can do, and put up your display in good shape, I am sure they would not be at all backward in giving you handsome encouragement; and this state of affairs is very much better than fault-finding. If, after having done all you can, they should get hold of a poor man for judge, and accord the premiums to a box-hive bee-keeper, don't find a bit of fault, but urge the importance next time of having a practical bee-man for at least *one* of the judges.

THE FOOD QUESTION IN WINTERING BEES.

FRIEND CORNELL TAKES FRIEND HEDDON TO TASK.

REPLYING to question No. 97, in GLEANINGS, Mr. James Heddon says it does not make much difference about ventilation, because the whole matter of safe wintering hinges on the food. Since, of the thirteen bee-keepers who send replies, Mr. Heddon is the only one who ignores ventilation as a factor in wintering, it is proper to inquire what are his views regarding food, upon which, in his opinion, hinges all the chances of failure or success.

Of sugar syrup he says, "It has heat-producing elements to a greater degree than honey." He says, "Syrup contains no nitrogen, but it does contain more oxygen" than honey, and he says this oxygen is burned to keep up the temperature. Of pollen, he says, "Pollen is almost wholly nitrogen," and "the consumption of nitrogen is the cause of the trouble." On this account he objects to honey, because it often contains floating pollen.

In a recent article, Mr. Heddon says, "When the bees find themselves unable to keep up the proper temperature by the burning of oxygen *derived from the honey and sugar syrup they consume*, they add to it combustion from that taken in in the air they breathe." Honey and sugar are built up of carbon, with twice as much hydrogen as oxygen. This is precisely the proportion in which these two elements are united in water. Neither the one nor the other plays any part whatever in heat production, when combined as they are in this case. That depends entirely upon the quantity of carbon present, and upon the requisite quantity of oxygen being taken in, by breathing, to oxidize it. The oxygen which takes part in heat production is not taken into the alimentary canal, and is therefore neither meat nor drink, but it passes from the air, taken in by breathing, into the blood by diffusion, and by diffusion also from the blood into the tissues; hence the necessity for a change of air in the hive, because "one pound of carbon requires for its combustion 158 cubic feet of air."—[Butler on Ventilation of Buildings.]

The quantity of carbon in one pound of sugar is

43 per cent of the whole. One pound of sugar, therefore, requires for its combustion about 68 cubic feet of air. Supposing the bees to consume half an ounce per day, or about a pound per month, and supposing the air space in a hive to be half a cubic foot, to furnish the oxygen absolutely required for the consumption of this small quantity the air in the hive must be changed in one way or another, at least once in every six hours. There is no escaping this conclusion. If this supply of air is cut off, the bees will die just as certainly as the machinery in the "Home of the Honey-bees" would stop if the dampers were closed and the furnace hermetically sealed.

I may mention, incidentally, that the oxidation of half an ounce of sugar in the bodies of the bees produces sufficient heat to raise the temperature of 23½ lbs. of water one degree. In both the above cases, the sugar is assumed to be free of water. Assuming their food to contain 12 per cent of water, which is about the normal quantity in honey, the oxidation of half an ounce of food would raise the temperature of 13 lbs. of water one degree. Since the quantity of carbon in honey and sugar is the same, their heat-producing powers should be the same, and experimental tests prove this to be the case.

The union of oxygen and carbon, besides generating a great amount of heat, produces a large quantity of carbonic acid, which is given off with the breath. To dilute this gas as fast as it is produced, so as to render it harmless, the air in the hive must be changed every half-hour, assuming the consumption of stores and capacity of the hive to be the same as before.

The quantity of vapor produced by the consumption of a pound of sugar can be shown to amount to about 16 cubic feet. This is an additional reason for a steady change of the air in the hive.

These statements of fact are in accord with the teachings of physiologists and scientists whose reputation is second to none in the world; and I would ask Mr. Heddon to investigate what is known regarding these facts, and be prepared either to admit their correctness, or to successfully controvert them.

"From the researches of Dr. A. de Planta, as to the chemical composition of hazel pollen, we learn that the contents of pollen grains consists of protoplasm, starch, and oils. After thorough drying, the residue remaining consists of 31.63 per cent of nitrogenous matter, 64.36 per cent of non-nitrogenous substances, and 4.01 per cent of ash. The non-nitrogenous portion contained no glucose, but cane sugar was proved to be present to the extent of 14.70 per cent, and starch to the extent of 5.26 per cent."—[B. B. J., 1886, p. 286.]

In an analysis of pollen given by the late Arthur Todd, B. B. J., 1883, p. 14, we find:

Water.....	12.74 per cent.
Ash.....	2.72 per cent.
Albuminoids.....	21.75 per cent.
Sugar.....	26.20 per cent.
Nitrogenous organic sub's.....	36.59 per cent.

Albumen, which is shown to be present to the extent of 21.75 per cent, contains about 15 per cent of nitrogen, or 3.26 per cent of the whole. The whole amount of nitrogen present was less than 40 per cent in this case, and less than 32 per cent in the former one. These analyses hardly justify any one in saying "pollen is almost wholly nitrogen." In the latter case the carbon in the sugar present

amounts to 11.27 per cent of the whole, and the carbon in the albumen present amounts to 11.52 per cent of the whole, or in all more than half as much carbon as there is in an equal weight of sugar. The other elements, nitrogen, sulphur, and phosphorus, produce some heat also. These facts show that, for direct heat production, pollen is not an unimportant item in the larder of the hive. According to the investigation of Erlenmeyer and Dr. von Planta, the average total quantity of floating pollen in ten different samples of honey was only about one part in 600 parts of honey. Regarding this, Pastor Schoenfeld says, "It is quite clear that so exceedingly small a percentage of nitrogen is altogether insufficient to maintain a colony in a normal and healthy condition during the winter."

I shall not now discuss the necessity for pollen to repair the wear and tear of tissue in bees from the time of fall feeding till the time for gathering pollen in the following spring, a period of, say, seven months, during at least a portion of which time it is impossible to keep them in a state of quiescence; but I shall direct attention to two facts to which other writers on food for wintering have not alluded, as far as I recollect; namely, that, under any circumstances bees can not continue to digest sugar syrup for any considerable length of time without the aid of nitrogen, and that the oil contained in pollen materially assists the digestion of both the nitrogenous and carbo-hydrate food stuffs. In order that the reader may judge as to the sufficiency of my grounds for making these statements, I quote as follows:

Dr. Letheby says, "It is very probable that the nitrogenous matters assist the assimilation of hydrocarbons. Fat serves important functions in the process of digestion, assimilation, and nutrition. The digestive power of fat is considerable."—[Lectures on Food, pages 71, 74.]

Dr. Parkes says, "If the nitrogen be cut off from the body, the various functions languish. This does not at once occur, for every body contains a store of nitrogen, but it is at length inevitable."—[Practical Hygiene, vol. I., p. 204.]

Dr. Wilson says, "The saccharine constituents are largely concerned in carrying on the digestion of nitrogenous substances."—[Handbook of Sanitary Science.]

Dr. Pavey says, "It may be inferred that nitrogenous matter is required, not only for the formation of tissues, but likewise for contributing, by the promotion of the requisite change, to the utilization of non-nitrogenous principles; and unless it exists in suitable amount in the food, these principles fail to pass to their proper destination. The presence of fat in the food seems in some way to promote the transformation of the carbo-hydrates. Fat exerts a favorable influence over the assimilation of nitrogenous matter."—[Treatise on Food and Dietetics, pages 278, 279.]

Prof. Foster says, "When an animal is fed simply on non-nitrogenous food, death soon takes place. The food rapidly ceases to be digested, and starvation ensues."—[Text-book of Physiology, page 570.]

These quotations are hardly compatible with the statement that "the consumption of nitrogen is the cause of all the trouble."

If practical proof of the truth of these statements is required when applied to the case of the bees, it is furnished in the experience of Mr. Heddon, as

given on page 270, GLEANINGS, 1885. His bees, from which pollen had been excluded as far as possible, died of starvation, notwithstanding the fact that they were found to be full of undigested sugar syrup. In the light of the information furnished by the physiologists quoted above, are we not justified in attributing their defective digestion to the absence of nitrogen and oil, which a supply of pollen would have furnished? Mr. Heddon found, then, for the first time in a long experience, that bees quite readily succumb to the effects of cold. When the digestion of sugar languished and then ceased, a failure in keeping up the normal temperature should excite no surprise. The experience of Mr. Demaree, given on page 788, vol. I., C. B. J., is another case in point, showing that bees can not continue to digest syrup without pollen.

In view of all the facts, I think it will be admitted that Mr. Heddon is in error as regards the composition of honey, syrup, and pollen, their functions in the process of digestion and assimilation, their capacity for heat production, and the necessity for a constant change of air in the hives. I submit, therefore, that he is not in a position to be able to say with confidence, "The whole matter of safe wintering hinges on the food." All attempts to defend the exclusion of pollen from the food of bees in winter, on scientific grounds, have broken down, and all experiments made to justify its exclusion, by the success of practical results, have been either so inconclusive that they are quite worthless as proof, or they have proven the very contrary of what it was supposed they would establish. I think it is high time that Mr. Heddon should begin to see that the old-fashioned food, honey and pollen, with surroundings such as will keep the bees comfortable, are, after all, the most reliable conditions for safe wintering.

S. CORNELL.

Lindsay, Ont., Can., Feb. 11, 1889.

Friend C., you are doubtless right, or pretty nearly right; and I presume likely that friend Heddon as well as myself has got somewhat rusty on chemistry. You have given us theory and science (and I believe you are correct) enough to last us a good long while. Now, while I do not mean to be disrespectful to science or theory either, I want to say that I have wintered splendidly when every thing was removed as closely as I could remove it, except stores of sugar syrup. In fact, we took their combs all away, and gave them clean combs containing nothing but sugar syrup, and I never saw bees winter better than they did. We have done nearly the same thing, on a large scale, since the time I have mentioned, and there was no loss with as many as 200 colonies. In this latter case, however, they had their own combs; in the former experiment alluded to they did not commence brood-rearing, or at least did not succeed in rearing brood, until they got pollen; and in regard to ventilation, I feel sure either that bees do not need as much as you estimate, or that more air gets through ordinary hives and ordinary cellars than we are aware of. I have repeatedly seen bees winter beautifully in ordinary cellars that seemed to be remarkably close and tight, where no provision had been made for ventilation at all; and with bees buried in the ground, or put in caves, as Doolittle mentions, they not

only do well, but even better, than where provision is made to have a constant circulation of air. We thank you for your excellent article, because it gives us valuable scientific data for future reference; but if practice and theory should give different results, I would stick to practice. Friend Terry said that, when scientific men were against ensilage, and the cows were for it, he preferred the testimony of the cows. I believe the cows have come out ahead.

CALIFORNIA: CONSISTENCY OF CHRISTIANS, ETC.

A GOOD BOOK ON THE SUBJECT OF TOBACCO-USING.

MR. ROOT:—I have delayed this letter, that Huber and all the home friends might have time to exhaust their store of questions in regard to that wonderful country you have just visited. My husband traveled over a part of the same country one year ago, and was so well pleased with it, and had such good times with J. Root, that he tells me he left his heart there. I think the orange-tree, with its fruit in all stages of growth, and from which ripe fruit may be picked every month in the year, might remind us somewhat of the tree of life, spoken of in Revelation. And did you never think, while admiring them and all the other beautiful things, what wonderfully large tobacco-plants are raised in that rich soil, whose leaves are not for the healing of the nations? No doubt you did, and were saddened by it. I have not seen much about tobacco in GLEANINGS of late, and I often wonder if all the tobacco-users who come under the influence of your journal have reformed, and if all the boys whose papas take GLEANINGS have been careful not to learn to smoke. I prize what has been printed in the "Tobacco Column" more highly than any thing else in GLEANINGS—not that I undervalue Our Homes, but there are a thousand people who will speak and write on the subject treated there, where one can be found who will say a word against the use of tobacco, except in a mild and general way; and so unpopular is it, that hardly a newspaper or magazine can be found that will print a decidedly outspoken article on the subject. And when we think of the number of professing Christians who are slaves to the use of tobacco, it is appalling; "their name is legion." I can count quite a number in our little neighborhood. They will "speak in meeting," and say they feel that they have reserved nothing—all is laid on the altar. Now, I believe these people are real Christians, but they have not been aroused on the subject; "their eyes they have closed," etc. I know a man about 30 years of age who has been a professing Christian for 15 years; has used tobacco all the time, and is Sunday-school superintendent in one of the churches of this place. I believe he has never been known to "take a chew" during the hour he is engaged in this exercise. He also teaches a district school near here; and although it is not known that he uses tobacco during school hours, he makes a free use of it morning, noon, and night, giving and receiving it from the boys of the school who are addicted to its use. Now, if it were possible to exclude all superintendents and teachers, what shall we say of Christian fathers who

have an influence over their sons that no teacher can have, and yet indulge in its use without apparent shame, and other fathers too?

I am very glad of what you are doing to bring about a tobacco reform; and may we not hope, when liquor has been banished from the land, and people are aroused on the subject, to see the boy who now walks proudly with a lighted cigar, slink out of sight behind a corner, or hide in an alley to indulge his morbid taste? And may we not look still further, and confidently expect a time when the American people will arise in their might and put it from them? Let us remember the words the Lord spake to Joshua, that the children of Israel should go up and possess the land—"Only be thou strong and very courageous."

I have been led to think more on this subject of late, by reading a book, written by an aged minister residing in this vicinity, whom I have known for years. I will send you a copy of the book. His object in writing the book was to inform the young of the evil effects of tobacco, both on mind and body. He has been studying the subject for a number of years, and finally decided to publish a book at his own expense, that the youth of the land might be warned, giving incidents from his personal observation, and opinions of eminent physicians, etc. He has not undertaken this work with a view to money-making, but solely to benefit mankind; and he assures me that, whatever profits are derived from its sale, will be used to print more books. While preparing himself for his life-work, he was a student at Oberlin for some time, completing his studies afterward. He has spent a long and useful life in the ministry, and now, in his old age, to help rid the world of this tobacco curse, he is willing to give the greater part of his earthly store. Surely a little of that spirit of self-sacrifice manifested by the Savior remains with his followers. The price of the book is 50 cts. Will you be so kind as to read it and give it such notice in GLEANINGS as you may think best? Please let me know. I wish every subscriber of GLEANINGS would purchase this book. All having sons opposed to the use of tobacco, and those having no children, could make it do a good work by placing it where visitors and hired help could easily pick it up; and those having daughters only could make it useful in the same way. I think it would be a good book for Sunday-schools and public libraries.

MRS. J. B. RATCLIFFE.

Amboy, Minn., Feb. 1, 1889.

My good friend, I am exceedingly obliged to you for having given us a good stirring-up on the tobacco reform. In the crowd of other matter that is sent in for GLEANINGS, we have sometimes inclined, when deciding what *must* go in and what *might* be held over, to say that the Tobacco Column is not of any special importance "for this present issue," so it lies over for something else. There is almost always, however, a protest by myself when a single number goes to press without at least something on the subject. I am exceedingly obliged to you for the copy of the little book, and I want to say to our readers that it is a perfect gem so far as the subject on hand is concerned. There is not any dry reading in it. It is all, or pretty much all, stories from actual experience. One is reminded of an experience meeting where those who attend rise up rapidly, one after

another, and give in their testimony. The book is so interesting that, if the hired man or boys should open it almost anywhere, they would read and read, and then turn back until they had read it through. I really believe, as you say, that it will pay us to buy it and leave it around where people will get hold of it. You may tell the author that I want 100 copies right away; and those who find it more convenient to order of us instead of the author, N. A. Hunt, Mapleton Station, Minn., can do so.

We will furnish it at 45 cents, by express or freight with other goods. Now, then, friends, if you want to help along in this work, order one or more copies, as you can afford, and "leave them around," as our good friend Mrs. Ratcliffe expresses it. The book is neatly bound, and contains 192 pages, so that the price, 50 cents, is not very high.

Since the above was in type we have the following:

Mr. N. A. Hunt:

I am glad to receive a copy of your book—a broadside against tobacco. I have read it from beginning to end, and believe every word of it. The book is fair and moderate in tone, without exaggeration or over-statement, nothing bitter or fanatical in it; yet it is a terrible arraignment of the mischievous and unworthy habit. I wish all the 5000 copies were sold, and another edition twice as large called for.

Jas. H. Fairchild, President Oberlin College.

It is refreshing to know that so great an authority as the President of Oberlin College so warmly seconds what I have just said in regard to the book.

RAMBLE NO. 11.

THE RAMBLER'S IDEA OF WHAT A BEE-SUIT SHOULD BE.

BEFORE getting off upon this ramble I wish to call attention to something else that is an immense success in my every-day work in the apiary.

So far in bee-literature I have not read of nor seen illustrated a really full dress-suit especially for bee-keepers; nor have I seen any thing systematic in dress in any of my rambles. The Rambler tries to be a tidy bee-keeper, and has given bee-keepers much attention.

A special work-suit must have several essentials. It must, or ought to be, light in color; easy to put on or off; must protect the entire person, and be of a color, make, and texture, to stand frequent washings.

Duck overalls and aprons usually worn are clumsy and inconvenient for all of the above purposes. Getting thoroughly disgusted with the "stickativeness" of my clothes I rambled to a clothing-store and found what is called an engineer's suit—overalls and short coat, or blouse, made of blue and white checked cotton cloth, the whole weighing only 1¼ lbs. Cost "zhust von tollar, zhust a fit, and zhust the thing." The beauty of this suit is the certainty of complete protection to your Sunday clothes if you choose to wear them; and the price enables you to own two suits, and wash often, and always clean. Then there are plenty of pockets fore and aft, for pencils, jack-knives, screw-

drivers, queen-cages, toothpicks, etc. There are those who may possibly object to appropriating or adopting an engineer's suit to bee-keeping; but, friends, if a mortal man or woman, conducting an apiary of two hundred colonies of bees, isn't an engineer, who else indeed is worthy of the name?

When extracting honey, or at work with stickiness that is certain to get on my arms, I put on an additional set of sleeves. What are called gossamer sleeve-protectors have been extensively advertised; but my experience with them proves them to be a humbug. Try to wash them off, and they wet through; then they are of such a stingy pattern that the elbow is not reached. I now use a sleeve made of a new manufacture of oil cloth, thin, flexible, and absolutely water-proof, reaching generously above the elbow, and secured at wrists and arms with a peculiar button. These buttons are also on the bottoms of the overalls and on the coat-sleeves. Rubber bands work well at first, but they soon become a "vexation of spirit."

THE RAMBLER'S COMPLETE WORK-SUIT.

For head wear I prefer a stiff straw hat, with a 3¼-inch brim, over which a silk brussels-net veil is worn in the ordinary way. A hat-brim of the above width enables the veil to give protection to the Rambler's three-inch nose. There are other bee-keepers who would probably need a wider-brimmed hat; but a slouch hat should be avoided, as partaking too much of the nature of a cow-boy style.

The Rambler could never tolerate a white veil with black portion before the eyes, as there is always more or less strain on the eye through the contrast of color; and then such a veil never remains half black and half white. The white soon tries to get to the shade of black, but never attains to it, but gets dirty enough to look very untidy. The Rambler has seen some horrid bee-veils, and, rather than wear them, would prefer stings.

To hold the veil snug around the neck I prefer a stout cord with a slip-noose. This isn't half the bother it is to tuck it under the coat; or if it is desired to put the coat-collar over, it is already drawn up nicely for the purpose by the cord. A net veil can be slipped off the hat, and carried in the vest pocket.

I am also particular in relation to foot-covering. I have seen bee-keepers stamping around the yard with heavy No. 10 cowhide boots, or even rubber boots, with the trowser-legs tucked in. This style may do for drawing manure, ditching, or other menial work, but are clogs to feet, body, and mind, in the bee-yard. There is nothing easier than a good lace or button shoe. I prefer a leather shoe for durability; and for wet mornings I slip on a pair of rubbers. Cloth shoes of various styles are very easy, but objectionable on the above grounds.

The foregoing, therefore, is the Rambler's ideas and practice in relation to bee-dress; and to keep up my reputation for liberality, I give it to the fraternity. Don it, my friends, and you will some day rise up and bless the

RAMBLER.

P. S.—Please wait a few minutes, friends. I will now start on the ramble as soon as I get "Nig's off hind shoe set."

R.

Friend R., I think you have hit the nail on the head this time, even if you did not ramble. When I am working among the bees, I can not bear heavy boots, nor heavy clothing of any kind. Our engraver has made a very neat-looking young man, as you may notice, in the picture. Your foot on top of the hive looks a little as if the pant-leg were tied up with a string. I used to wear cloth or kid gaiters; and when in a hurry I have often wrapped up the leg of my light pants, and pulled my stocking over it. This made a sure thing of keeping the bees out, but it did not look very becoming, especially when ladies called to see the apiary. One trouble about dressing, especially for our vocation, is that most of us have to rush from one thing to another in a hurry. Ditching, hauling manure, etc., may be the regular work of the day until something calls us to the bee-yard, or we happen to have a little spare time. I have often admired the suit worn by our railway engineers, especially when they put on a clean one, and I believe the same rig would be handy and convenient for a good many kinds of farmwork.

THE HONEY EXHIBIT AT THE COLUMBUS CENTENNIAL.

PRESIDENT MASON GIVES FURTHER FACTS CONCERNING IT.

FRIEND ROOT:—In GLEANINGS for Dec. 15th I described your exhibit at the Ohio Centennial Exposition, as shown in the picture on page 959. I think I am safe in saying that not one-fourth of your exhibit is there shown, and I will but briefly mention the remainder.

Across a passageway, to the right of your exhibit as shown in the picture, on a platform, was shown a one and a two story chaff hive all complete for extracted honey, and so arranged that, at the desire of any interested visitor, some of us were ready to transform either or both into hives for comb honey in a "jiffy." Here was also displayed a bee-tent made of mosquito netting; a roll of 600 square feet of wire cloth; a large roll of perforated (or queen-excluding) zinc; some force-pumps, sections, etc.

On the further side of the table, but not to be seen in the picture, there were smokers, sections in

all shapes; foundation, both thick and thin; foundation fasteners, ready for business, and they were frequently put to the test too. There were also price lists, and sample copies of GLEANINGS, hundreds of which were distributed. On this table, and within easy reach, was always kept a goodly supply of your cards offering \$1000 for evidence that comb honey is made by machinery.

On the platform beyond the table was a large assortment of Langstroth and Simplicity hives in all sorts of combinations; slatted honey-boards, metal honey-boards, wood and zinc honey-boards, wooden frames, metal-cornered frames, chaff cushions, division-boards, separators, section cases in endless variety, with and without sections, and with and without starters. It was just wonderful what a variety of combinations could be made with what was here shown. Wondering and inquisitive bee-keepers could in a moment have a hive rigged out for operation. It was as good as a box of monkeys, for fun, to see your men or some one else of our company make up a hive for any purpose, or to suit any inquiry.

Two kinds of section-folders were always in running order; and boxes of sections, made on your section machinery at Power Hall, were always handy by so as to demonstrate to visitors and customers just how it was done.

One day when we were all busy showing off things to the crowd, some boys took it upon themselves to fold a lot of sections with one of the machines, and, when first noticed, had folded as much as a two-bushel box full. Perhaps if they had thought it was work they might not have folded more than a dozen or two, and then have been "tired out."

On the platform, at the left of the picture, were shown some 60-lb. honey-cans with their accompanying boxes; a lawn-mower that was so cheap and good that I brought it home with me; a solar, a Swiss, and a Jones wax-extractor, and some swarm-catchers.

Next to the display of queens, I don't now remember of any one thing that you had on exhibition that attracted so much attention, and called forth so many remarks, as did the straw bee-hive you took the trouble to get from Connecticut, I believe. We had it labeled, "Straw bee-hive over one hundred years old." People were not satisfied with looking at the outside of it, but had to turn it over and look inside also; and when we would tell them it was the same shape inside as out, they would still turn it over. I sometimes wished that it contained a colony of bees that were first class in the stinging line.

A great nuisance at such times is the very bad habit so many people have of leaving things just as they happen to be when they get through examining them, evidently not having "a place for every thing, and every thing in its place" at home.

The large sign, "Exhibited by A. I. Root," in the top of the picture, looks all out of proportion to the rest of the exhibit; but it was not, and I have not the slightest idea why it looks as it does. It was a neat, tasty, and cheap sign, and all the exhibits would have looked better with a nice sign over them.

Perhaps some exhibitors may want to have such a sign at some county or State fair next fall, but might think it is too expensive. Aside from the boards, either rough or dressed, the cost is but a few cents. Mr. Will Weed, who had charge of your exhibit, was

quite anxious to have everybody know that the exhibit belonged to A. I. Root, and seemed bound to have a sign painted that would have cost several dollars, from four to six, I believe; but "older heads" didn't think it was best; but he could not give up his wish, and so took two boards, about nine inches wide and six to eight feet long, and fastened them together with strips on the ends, and covered the whole, both sides and edges, with white paper. He then took some red card-board and cut it into strips and pieces, and then tacked them on with small tacks, making the name A. I. Root, as shown, the A being made of three pieces, the I of one, the T of two, the R of seven, and the O's of eight each. These letters were put on both sides, and it made a very neat sign. I believe the above letters were about a foot high. The letters in "Exhibited by" were each of one piece, and were about three or four inches high.

To the left of the picture and your exhibit was quite a variety of appliances used in the apiary, consisting of an exhibit by Dr. G. L. Tinker, in which was a box hive used over 40 years ago in Eastern Ohio, and a small straw hive that was used over 60 years ago in the same locality. The doctor also exhibited a double-walled hive, several of his "storifying" hives, for either comb or extracted honey, several section and extracting supers, quite a variety of honey-boards, among them his wood and zinc queen-excluding; strips of perforated zinc; four-piece poplar sections, smokers, cartons, drone-traps, some crates of poplar honey, two colonies of his Syrio-albino bees, and three nuclei for showing queens. To those who have seen any of the doctor's "handy work" it will be unnecessary to say it was first class in every respect.

Dr. J. C. Oldham, of Springfield, O., exhibited an invertible and divisible shallow-framed storifying and interchangeable hive that attracted some attention, and was frequently dissected by curious bee-keepers. Near by was an Armstrong side-opening hive and side-opening T super, with sections, fixed up in nice shape, exhibited by E. S. Armstrong, Jerseyville, Ill. It attracted quite a good deal of attention, and we frequently had to put it together after parties had given it a good overhauling, or visitors would not have known such a hive was on exhibition.

Here, too, was one of Mr. James Heddon's new hives, with divisible brood-chamber, section-supers, extracting-super, a queen-excluding and a break-joint honey-board. This hive was a regular "curiosity shop" to many, and attracted much attention, and, like the other divisible hives, had frequently to be reconstructed so that its individuality might be maintained.

Here was also a straw hive from Germany, which belonged to an 80-year-old German by the name of Burchard, who lives in Michigan, and who will keep bees in no other kind of hive. It was a great curiosity. With it was an old Quinby smoker that belonged to Mr. Andrew Fabrique, also of Michigan. It was brought from Pennsylvania many years ago. By the side of this hive was an old "log gum," or bee-hive, cut from a basswood-tree, with a board nailed on one end for a cover, for which many old bee-keepers had words of affection, and many an entertaining as well as amusing story was told about cutting bee-trees by these "old-timers." These old relics were properly labeled, so that passers-by might know what they were.

Here I'm reminded of an explanation given one day by a gentleman 75 years old, being one of our largest exhibitors, a well-posted bee-keeper, and known to us as "Uncle Aaron" Goodrich, of Worthington, Ohio. Some visitors, who acted as we see people sometimes when they wish to make the impression that they are smarter than most people, were asking him some questions about the straw hives, the box hive, and the log gum, and he told them that was "the kind of hives bees used to be kept in when they had king-bees;" then pointing to the Tinker, Armstrong, and Heddon hives that were near, added, "but those nice hives, or bee-palaces, are what bees are kept in now that they have queens." Perhaps there didn't any of us bee-keepers or anybody else smile, and it can readily be imagined that the story was more than once repeated.

On this same platform were exhibited a Muth honey-extractor and a Jones wax-extractor by Dr. Besse, of Delaware, O., and a solax wax-extractor and bee-hive by Elias Cole, of Ashley, O.; also a hive and solar wax-extractor by C. E. Jones, of Delaware, O., each of whom also exhibited several good colonies of bees and a one-comb nucleus to show the queen, and one of them had 16 and the other 17 queens in queen-cages, for exhibition.

In the right-hand upper corner of the picture on page 959, above referred to, is shown a portion of the exhibit of C. E. Jones, which consisted mostly of comb honey in crates, the crates being interspersed with extracted honey in different styles of packages, and a display of honey-producing plants. He also had two candy-jars that had been filled very nicely with honey by the bees.

To the left of the above exhibit was that of Mr. Elias Cole, of Ashley, Delaware Co., O., composed largely of extracted honey in glass, and placed on shelves. It will be noticed, by referring to the picture, that some of the bottles look black and some white. That is owing to the different kinds of honey. When the picture was taken, that which is white was candied; and the other, which is alsike-clover honey, was not. The wall above the exhibit was decorated with flags, etc.; and over the left portion of this exhibit, almost entirely hidden by the large sign, was festooned a large American flag. To the right and near the top of the wall may be seen a display of over 140 honey-producing plants, each one numbered and named.

On the platform below the exhibit, but hidden from view, was a foundation mill, smokers, honey-knives, samples of foundation, comb honey in crates, beeswax, etc. Near the center, at the bottom of the shelves, may be seen a part of a diminutive house that attracted the attention of all the little folks who espied it, and many an "old folks" was attracted by its novelty. It was a regular house made in the form of an L, with chimneys, doors, and windows. Lace curtains were at the windows, so looped back as to show the nice honey within. It had a veranda, with diminutive people sitting on it; a pump near the door; a fence around the dooryard, which contained evergreens and shrubbery, and, to complete it as the home of honey-bees, small bee-hives were sitting in the yard. To complete the picture, a sign, "This Property for Sale," was standing in the yard.

At the left of Mr. Cole's exhibit may be seen a portion of the exhibit of our family, consisting of comb and extracted honey, honey-plants, honey-

cakes, and cookies of several kinds, honey-candies, honey vinegar, honey wine, honey-knives, foundation, beeswax, and Bingham smokers sent by Mr. T. F. Bingham for exhibition. At the right of the exhibit, but hidden by your Sturwold show-case, is another of your Sturwold cases filled with fine comb honey, and, standing on its top, one of Mr. E. O. Tuttle's bee-keepers' medleys.

A description of what was on the other side of the building, and of your section machinery, etc., with some incidents connected with the exhibition, may be given in the future. A. B. MASON.

Auburndale, O.

Now, doctor, I am going to complain a little. From the above it is quite evident that, day after day and week after week, you explained things, and showed your visitors all around—told them long stories; yes, you even took pains with every old lady, and I suppose every juvenile too; and yet when I came around myself you did not show me about nor tell me any of these wonderful stories at all—at least if you did I can not remember it—that is, I do not remember very much about it. I did not know until just now that there is a bee-keeper in Michigan who still keeps bees in straw hives. You say the man's name is Burchard, and that "he lives in Michigan;" but how in the world are we going to visit and see an old-time apiary, without knowing what part of Michigan it is in? I want to tell you, friend M., that Michigan is a very big place. Your story is so interesting that I feel now as if I would give a good deal to see "Uncle Aaron" and all the rest of those other good friends we always meet at our Columbus conventions. By the way, I have just asked Ernest why we did not have a convention this winter. He says we had our convention in conjunction with the great national, and the bee-keepers thought that that was convention enough for quite a spell. I do not agree with him, however, and I hereby give notice that, when there is another Ohio bee-keepers' convention, I wish to be invited.—Just a word about that sign. Mr. Weed wrote me that he thought we ought to get a good nice big sign, even if it cost several dollars. I told him that I thought something transient would do very well. But when I got down there I said to myself, "There, the boys have gone and paid out quite a lot of money for a sign, after all," but as we went there to have a picnic I thought I would not scold, but just make believe that I was pleased, you know. Pretty soon I remarked to Mr. Weed, "Why, Will, you did go and get a nice sign, after all, didn't you? But, didn't it cost a good deal of money?" And then they had quite a good laugh when somebody said it did not cost half a dollar all together. Now, friends, you can make very handsome signs, to be put up indoors, not exposed to the weather, with a pair of scissors, some tacks, and some colored paper. Why, there was not a prettier nor a plainer sign on the whole centennial grounds than that one.—Doctor, you do not tell us who got up that little house and dooryard, etc., with the house "chuck full" of honey. Did that little sign bring a customer?

HEADS OF GRAIN FROM DIFFERENT FIELDS.

DR. A. B. MASON'S OPINION OF THAT NEW PRESS STRAINER.

I AM glad you have the press strainer for sale, that you illustrate and describe on page 130; and so cheap too. I told one of your men at the centennial that you ought to have them for sale. At the earnest solicitation of "Uncle Aaron" Goodrich, one of the exhibitors at the Exposition at Columbus last fall, who lived nine miles away, I went home with him one Saturday night to spend the Sabbath with him and his family; and nicer potatoes than were on their table it had never been my privilege to eat. (I hope Mrs. Mason will not hear of this.) Monday morning at breakfast I got up courage enough to ask for their way of fixing them so nicely, and learned that it was done with just the kind of press you describe. They had been sold from house to house by an agent, for one dollar each. I found them for sale at a "general store" near where "Uncle Aaron" lived, and bought one for fifty cents. I would have willingly paid a dollar for it, and felt that I had the worth of my money. Mrs. Mason makes as nice bread as I ever tasted (I don't care if she does hear of this), and uses mashed potatoes in doing it; and when I showed her how the press (or "tater smasher" I call it) made the potatoes so "fluffy" you "just had oughter seen" her smile. Try to induce every husband to get one for his better half, and every "feller" to get one for his "best girl," if her father hasn't already got one for her mother.

Auburndale, O., Feb. 20, 1889.

A. B. MASON.

CONTRACTION, AND HOW FAR IT MAY BE CARRIED
WITH ADVANTAGE.

If the brood-nest is contracted to 5 or 6 frames in the Gallup hive, will the queen be more likely to lay in the surplus apartments? If so, is not side storing preferable? Do bee-keepers always use queen-excluding honey-boards if contraction is practiced? When the brood-nest is well filled with brood in the spring, is it advisable to spread the combs and insert about two empty combs in the center, in order to increase brood-rearing?

E. S. MEAD.

Olivet, Belmont Co., O., Feb. 6, 1889.

Friend M., if contraction of the brood-nest is carried to extremes, of course there will be a greater liability of the queen going above to deposit eggs. If the colony is good and strong, a brood-nest of 8 Langstroth frames ordinarily will not require to be contracted. With a colony of moderate strength, and in a moderate honey season, it may be desirable to reduce the brood-nest to 5 or 6 frames.—As we have had but very little experience with the Gallup frame, we could not advise you in regard to contraction for a frame of that dimension.—Queen-excluding honey-boards are, we think, an advantage where the brood-nest is reduced to $\frac{3}{4}$ or possibly $\frac{1}{2}$ of its full capacity. A great many prominent bee-keepers do not consider their use essential, while others are just as positive that they are an advantage. In regard to spreading brood, we advise you to see an article from the pen of G. M. Doolittle, in a late issue,

SQUARE VERSUS ROUND PACKAGES FOR 10 LBS. OF EXTRACTED HONEY.

Last fall, when I was visiting some of the towns of Texas in which so much California honey had been sold two years ago, I found nearly all the merchants pleased with and wanting the California style of packages for extracted honey; namely, the square tin can holding 10 lbs. of honey, packed 12 in a crate, and sold by the dozen. I promised some of them the packages for the coming season; but where can we get them? You don't sell them, as it seems. I called the attention of some of the merchants to the fact that there was only 10 lbs., light weight, but they said they didn't care for that. I hope the editor will look well into this matter. Give us these packages at a fair rate, and we can compete with California in extracted honey.

Bright Star, Ark., Jan. 1, 1889. T. J. MARTIN.

We can furnish the one-gallon square cans put up ten in a box, and shipped from St. Louis, Mo., or from Medina, Ohio, in lots of ten boxes, at \$1.40 per box; in lots of one hundred, \$1.30 per box. Although we have not heretofore advertised them, the new edition of our price list will contain prices about as above. You will notice that the prices quoted are about the same as for the round cans of the same capacity. For economy of space, convenience in boxing and shipping, the square style of cans is very much superior. These and other considerations will make them the favorite shipping package for holding about 10 lbs. of honey. See another column.

STIMULATING BROOD-REARING WITH RYE FLOUR.

Can I start brood-rearing with rye flour, without feeding honey or syrup? When there is plenty of sealed stores in the hive, about what amount of the rye flour would I need for 55 colonies, to have them in good shape for the honey-flow? White clover and wild raspberry are the staple honey-plants here. There are several good orchards within range, and sumac is plentiful. Basswood is scarce.

Myrtle, Pa.

E. A. PRATT.

You can start brood-rearing with rye flour, without feeding any honey or syrup, provided the colony has plenty of stores in the hive. If the season is favorable for meal feeding—that is, if natural pollen is slow to make its appearance—you may feed several bushels of rye flour to your bees before the pollen comes; but we are not quite agreed that there is always a positive advantage in feeding rye flour. I have known bees to store so much rye meal in their combs that they did not succeed in getting rid of it, and it remained there the season through. Better not overdo it.

SUCCESSIVE SWARMS OCCUPYING THE SAME PLACE OF CLUSTERING.

Are swarms attracted by the scent of other swarms, or why do they so often cluster on the same object? During the past summer our swarms, with few exceptions, settled on the same tree (a peach-tree), notwithstanding there were other trees of the same kind in the apiary. I have hived as many as four swarms from the same tree, in a single forenoon. In fact, it became such a common occurrence that, when a swarm issued, it was easy to guess where it would alight. This state of affairs continued until the poor tree really became an object of pity, being almost destitute of

limbs. As many of the swarms were quite large, their weight was more than the tender branches could bear, and many of them were broken off.

SARAH E. DUNCAN.

Lineville, Iowa, Feb. 12, 1889.

The fact you mention has been brought up before, a good many times. You will find it spoken of in the A B C book. The subsequent swarm was probably attracted by the scent left by the bees and queen of the preceding swarm. Little particles of wax may sometimes be found attached to the limb, and these particles may be a factor in inducing the bees to seek this point.

LARGE OR SMALL HIVES FOR BUSINESS.

Friend Root, you have asked me a question in GLEANINGS, page 61, that I am just prepared to answer from actual experience. May 11th I cut a beehive, and there was about a quart of bees in it, and about 5 lbs. of honey. I put the bees and honey in a box with 6 frames 9 inches deep, and 17 inches long. I carried them home, set them on a bench by the side of a strong colony in a 10-frame hive. The small colony filled their 6 frames full by July 17th, and I put on top 24 1-lb. boxes, and they filled them. The 10-frame hive swarmed twice, and made just 6 1-lb. boxes full, and the first swarm made enough to winter on. The second swarm did not. In this case the small swarm is the better.

Wistar, Pa.

SETH NELSON.

Friend N., you give us good proof that a small colony may do better than a large one; but we should by no means conclude that this is the case in the majority of instances.

SOME GOOD NEWS FOR BEE-KEEPERS WHO HAVE TO PAY FREIGHT RATES.

Friend Root:—The bee-keepers of our country will be gratified to learn that one of the great railroads, the Louisville & Nashville (reaching from Cincinnati to New Orleans, to Memphis, St. Louis, and many other important points) issued a new local freight tariff and classification table last month, and a good many changes were made in our favor. The rates are not materially changed, but the new classification of articles in our line is what makes the reduction. For instance, "Bee-hives, set up," are changed from double 1st class to 1st class; same in the flat, crated, from 3d to 6th class (which is the same class as box material and lumber); honey, from 2d class to "honey in glass or tin, boxed," also "comb honey boxed," 3d class, if released, "honey in barrels or kegs," 5th class, released. All honey is 1st class if not released. Honey-extractors, crated, and smokers, boxed, are 1st class; beeswax is changed from 2d to 3d class. A "low tariff" letter from your humble servant to the General Freight Agent, about 3 months ago, may have dropped in opportunely, as the new tariff was being made up; and may or may not have had something to do with the changes. That matters not, though. The result of the revision is gratifying to us bee-people, and we appreciate it enough to "stand by" the "old reliable" L. & N., and give her our traffic whenever we can.

Wetumpka, Ala., Feb. 4, 1889. J. M. JENKINS.

Friend J., this is indeed good news, and we hereby express our hearty thanks to the L. & N. Now, then, can't their tariff rates be submitted to other roads, as a means of inducing them to go and do likewise?

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

All queries sent in for this department should be briefly stated, and free from any possible ambiguity. The question or questions should be written upon a separate slip of paper, and marked, "For Our Question-Box."

QUESTION 109.—*Do the drones subserve any useful purpose in assisting to keep the brood warm after swarming?*

Sometimes.

GEO. GRIMM.

I think they do.

DR. A. B. MASON.

I believe that they do.

CHAS. F. MUTH.

I have always thought so, when natural swarming is allowed.

P. H. ELWOOD.

I seldom find sufficient numbers of them left in the hive to affect much.

R. WILKIN.

I guess so, but I am not sure. Let the apicultural entomologists post us in regard to this.

JAMES HEDDON.

Not any more than the workers that could be raised in their space and with their food.

DADANT & SON.

I suppose enough drones would keep the brood warm without any workers; but I think the same number of workers would do it as well, at less expense.

C. C. MILLER.

They may at times, when it comes off cold immediately after a swarm issues; but I think the cases are rare where the drones are of any use inside the hive.

G. M. DOOLITTLE.

Of course, all bees help keep up the temperature of the hive; but I should much prefer workers to drones. I am sure that few drones in the hive is the correct policy.

A. J. COOK.

I think it very doubtful. If they do, their use is not appreciated by the rest of the colony, as they are generally required to move into some corner of the hive, out of the way.

H. R. BOARDMAN.

I think they are of some assistance. I advise a limited amount of drone comb in each hive. I think all of the facts will not warrant the supplying a large number of drones.

L. C. ROOT.

I think the brood has sufficient vital heat of its own to keep warm, usually, in swarming time. In case the hive was a very bad one, or an untimely cold spell should occur, the drones might be useful.

E. E. HASTY.

I have failed to come to any conclusion in that regard, but I am inclined to think that they do not. Take a colony and sift the drones out, and another with drones, and you will see that one does as well as the other.

PAUL L. VIALLO.

Possibly they are of some use for this purpose, but their presence can generally be dispensed with without any detriment, as, at the swarming season, the weather is usually so warm that a very few bees will keep up the temperature of the hive. I have known a drone to hatch after lying on the top of a hive in the shade for three days and nights, no bees having been near it during that time.

JAMES A. GREEN.

The answers to these questions remind me of the time when I used a queen-nursery made of a lot of cages, so as to have a dozen

or two queens in one hive. When the queens were old enough to get fertilized I let them out one at a time, to take their wedding-trip. It all went very well until the bees protested against having a new queen every day or every other day. They began to ball them to such an extent that it spoiled the business. As a remedy, I proposed to have a colony all drones and no workers. The drones would keep the brood warm, and afford the new queen a refuge. Of course, they would not care a cent what queen nor how many queens there were at a time in the cluster. Well, it all proved true, and more too, for they did not care a cent how many robbers came in and loaded up and went off. My next project was to find a locality where no bees were near enough to rob; but as I did not at that time find any such locality around here, my plan of raising queens about as easily as you raise cabbage-plants went by the board.

QUESTION 110.—*Suppose two or more commission firms in the same city—distant from your home—solicit consignments of honey from you, and you know them to be equally reliable and capable. They watch arrivals, and know to whom your honey goes, in that place at least. They are not confined to your honey alone, but have consignments from others as well. Would you ship all your honey (for that market) to one of these firms, or divide your consignments between them? Give reasons for your decision.*

I think I would deal with one. This would involve less expense and trouble in the whole transaction.

A. J. COOK.

I would not ship to either, but employ my leisure moments in selling it at home and in the vicinity of home.

MRS. L. HARRISON.

Under the above circumstances I would ship to both. Two salesmen, each with a line of customers, are better than one.

GEO. GRIMM.

I would ship to only one commission house in the same place. You can not afford to enter into competition with yourself.

H. R. BOARDMAN.

Divide consignments, because there is a better chance to make your name known, and because you can best tell which firm is best.

DADANT & SON.

My custom has been to send or sell all to one party, as I prefer to receive one full remittance. There might be reasons for dividing shipments.

L. C. ROOT.

I would divide the consignment, believing that each would be interested in making better returns than the other in order to secure further consignments.

R. WILKIN.

If I could get no information as to which one has done the best, I would divide to find out. I have divided my shipment on some occasions, shipping on the same day, and the returns were at least 15% difference in price sold, although the honey was all of the same grade.

PAUL L. VIALLO.

In one city, I would confine my consignments to one firm, under ordinary circumstances. Reason: To prevent competitive ambition. I have seen the case in our city, where a carload of comb honey was consigned to two commission merchants, who ran down the prices of each offer in order to effect sales.

CHAS. F. MUTH.

If the crop were a small one I would send it all to one, in accordance with the proverb that says, "Don't make two bites of a cherry." Were the crop large I would send some to each, in accordance with the proverb that says, "Don't put all your eggs in one basket." Too many men in the honey-trade tends toward cutting under in prices. Too few men in the honey-trade tends toward an imperfect cultivation of the market. E. E. HASTY.

I would ship all to one firm. By so doing, the one who gets your consignment will feel better toward you than if you divided it. There are reasons both ways as regards the action of the commission merchant; but it is much less trouble to make one deal than two. We country people are too much prone to suspect the action of business houses in the city. In many cases we make ourselves ridiculous in that way. JAMES HEDDON.

That's a tough one. I've practiced both ways. I would ship to one firm alone, because it would be less trouble; and if small shipments, a little less expense; the firm would have a more friendly interest in my sales knowing they had all my shipments, and my honey would not be in competition with itself.

I would ship to both, so each would try to outdo the other in getting me a good price, and to find which one would do best for me, and because each may have his own customers. C. C. MILLER.

Of late years I have never shipped more than 500 pounds of honey to any one commission house, and have found that I obtain better prices than I formerly did. The principle seems to be, that there are more parties that want only from three to five hundred pounds of honey than there are who want larger lots; and where one sale will dispose of a whole lot at one time, the commission merchant prefers it that way, to the breaking-up of a large lot. If the commission merchant is honest and reliable, he should work to your advantage, whether he knows that he has your whole lot or otherwise. G. M. DOOLITTLE.

I think I should ship all to one firm. I have had no experience in sending honey to commission men; but if they all feel as do the commission men here in Toledo in regard to other kinds of consignments, it would be much better to send all to one firm. There are two good reasons for doing so. One is, that the commission man is more interested in the disposal of the consignments of parties who give him all their trade. Another reason is, that it tends to raise the price. If one has consignments and the other has none, he will feel like offering an advance in price, in order to secure a consignment. DR. A. B. MASON.

I would do as I thought right and best. The reason is, that, if your venture proves a bad one, you can say to your wife or other guardian that you did it for the best, etc. 1. I would send an equal quantity to each, with the understanding that the one who makes the best returns shall have a prize—either a chromo or a mouth-organ. 2. I would send all my honey to one; for if you let them both have it, the first thing they will do will be to run down the price; Jones will come in and say, "I can get Smith's honey over at the other shop for 10 cents a pound." Shopkeeper No. 2 will say that he will sell you Smith's honey for 9 cents. In a short time the price will be away down below the cost of furnishing

—another illustration of overproduction, and that prices are regulated by supply and demand, and not by trusts, monopolies, combinations, strikes, and tariff. 3. I should not send any thing to either of these men, but I would sell to the man who offered me a reasonable cash price. This is the only good way to establish a satisfactory honey-market. When nine-tenths of our honey-producers do this, we shall have a satisfactory honey-market, and not before. If you send no honey to either of these men, you will probably know enough to keep away from that town, as "they watch arrivals." P. H. ELWOOD.

Ship to only one commission firm in the same city, if you know that one to be reliable, otherwise there is likely to be competition and underbidding. This is especially the case if there is any difference between the two lots. Call one commission man A and the other B. Jones ships No. 1 honey to A, and some not quite so good to B. A's judgment is, that he can get 16 cts. for his lot of honey, while B puts a price of 15 cts. on that consigned to him. Smith, a sharp unscrupulous buyer, goes to B, inquires the price of that lot of honey, and is told 15 cts. He moves on to A, and prices Jones' honey. "What, 16 cts.? Why, I can get just the same honey down at B's for 15." A doesn't want to be undersold, so he probably replies that he will sell honey as cheap as B. Perhaps, to make a trade, he offers it at half a cent less. Back goes Smith to B, and says, "See here; A is selling honey at 14½ cts. that is a good deal nicer than this, worth fully two cents a pound more. If you'll come down to a reasonable figure, I'll take five cases of this; but if you can't, I'll go somewhere else." The result is, that Jones's honey, in competition with itself, lowers its own price. JAMES A. GREEN.

I do not know who asked the above question, but I suspect it was somebody who felt a little sore over some transaction, and wanted to see whether we as a crowd were sharp enough to pick out all the points in the case; and it is those who have had a rich and ripe experience who see difficulties first. For instance, our good friend Muth is the first one to see the danger that your stock of honey will be running against itself. Friends Elwood and Green develop this state of affairs still further. Friend Hasty tersely puts it by directing attention to the two dangers by referring to two opposite proverbs. Friend Heddon closes with a grand truth. We country people are too prone to suspect the action of business men in the cities. Wholesale denunciation of commission men is one of the saddest blunders a body of bee-keepers ever fell into.

QUESTION 111.—Which will make the better working colonies during the working season—that is, secure the most honey—those that require from 20 to 25 pounds to carry them through, or those that will get along on from 5 to 10 pounds while in winter quarters?

I think as a rule, such as consume the lesser quantity are the better. L. C. ROOT.

A strong colony always consumes more honey than a weak one, and a strong colony always secures the most honey. CHAS. F. MUTH.

I suppose this question has reference to large or small colonies; if so, I should say the large one.

The one that has the most bees will make the most honey.

E. FRANCE.

As a rule, those that winter on a small amount of honey in proportion to the number of bees in the hive; or, in other words, those that hibernate most perfectly.

P. H. ELWOOD.

Under the same conditions, the colonies requiring most honey for wintering will prove the most profitable the next season. Taking every thing into consideration, though, I do not care for extra-strong colonies in the fall.

J. A. GREEN.

It all depends on the queen. If the strength of the colony, when it goes into winter quarters, is the gauge of the prolificness of the queen, then the strong colony would likely make the better working colony, as the queen, judging by the past, would likely be the better layer of the two.

MRS. L. HARRISON.

The colonies that require the greatest amount of stores to "carry them through," as a rule will be able to do the most work during the honey-season, because most of the stores consumed are in brood-raising; and the colonies that raise the most brood will, as a rule, be strongest at the beginning of the honey season.

H. R. BOARDMAN.

I do not think this question can be answered, as so much depends upon the mode of wintering and quality of queen. I prefer to have a colony eat but little in winter. This indicates a repose or restful condition, that I think favorable to the bees. Disturbance or disquiet causes undue eating.

A. J. COOK.

It is not the amount of stores a colony consumes in winter quarters that enables the bee-keeper to judge of its working qualities. Some of the best working colonies I ever had consumed less than seven pounds of stores while in winter quarters. One of my poorest colonies last season was one that lost over 20 pounds in weight while in the cellar.

DR. A. B. MASON.

That depends. If the 25-pound eaters are ravenous because they are worrying and unhealthy, they will be very apt to come out number two in the honey-harvest. If they use the extra stores in rearing brood, they may gain or may lose by the process—more frequently the latter, I think. I rather prefer that all over 16 pounds be hanging in the comb-closet, to be given back to them in the spring, if desired. Bees that (in a moderate climate) will not go through the winter on 16 pounds had better be dead than to live and propagate their greedy race.

E. E. HASTY.

Our bees have always wintered the best when coming through with the least depletion of numbers, and consequently with better vitality where the consumption of stores, while in winter quarters, was small. We know by careful weighing that we once wintered a strong colony of bees, in a special repository, on two and a half pounds of honey. That season all colonies consumed a minimum amount of stores, and nearly all were strong enough to swarm about the 15th of April. I never saw any thing like it before or since.

JAMES HEDDON.

That depends. If the colony that eats 25 lbs. is no stronger than the one that eats the 10 lbs., but eats more only because it's uneasy, it is likely to come out weaker in the spring than the one that eats 10. Still, it is barely possible (although I don't

think it's likely) that, being of equal strength, the one eats more than the other because of a more active temperament, and on that account may be more active in the working season, hence more valuable. In general, however, I suspect that the colony that eats 25 lbs. is just so much stronger than the one that eats 10, in which case the one that eats the 25 is likely to be the better working colony.

C. C. MILLER.

Now, I wonder who is the author of these questions. What has the amount of the consumption of winter stores got to do with the working qualities of the colony during the next season, any way? How can we reason from an effect when we don't know the cause? Increased consumption of stores may be due to the temperature, the manner of wintering, disturbance, extra strength of colony caused by great prolificness of queens, etc., and it may result in "playing out" the queen prematurely, or it may continue the colony strong during the season. In other words, I don't think any judgment as to the working quality of a colony can be based on its consumption of winter stores alone. The colony in best condition *when the honey season opens* will ordinarily give the best results.

GEO. GRIMM.

To answer this question we had better condense what a successful bee-keeper of Italy, Mr. G. Metelli says, who got a good crop last year while bee culture was a failure in the whole country. See the *Apicoltore* for December and January:

"We use very capacious (capacissime) hives, which contain in the brood-chamber from 12 to 15 Italian frames, instead of 9 or 10, as usually." The Italian frame is about of the same size as the Langstroth, but it is placed vertically. "The colonies which, on the first of May, have hardly consumed the 22 or 24 lbs. (10 or 11 kilog.) of honey given for winter are not strong enough to make honey in spring. But we can anticipate that those which consumed from 36 to 40, and even 44 lbs., will return the honey used, and profusely."

DADANT & SON.

No colony, to winter well, should consume more than ten pounds of honey while in winter quarters. If more than this is consumed, the chances are against that colony being a very profitable one the next summer. By winter quarters, I mean the time during which the colony is in the cellar, or from Nov. 1st to April 15th. If this colony is wintered outdoors, then I should say from Nov. 1st to March 20th. After this, during the next two months, the colony should consume as much honey, if they are to be a profitable colony during the summer, as they did while in winter quarters. The size of the colony has not so much to do with the amount of stores which they consume while in winter quarters, as has the quietude or uneasiness of the colony. For summer profit, give me the colony which has been quiet during winter, every time.

G. M. DOOLITTLE.

No wonder our good friend George Grimm wonders who the author of these questions is. I suspect that A. I. Root started the matter, and I was pretty sure of the truth of what the above testimony brings out; namely, that uneasy colonies often consume a large amount of stores, without being very much the better for it; also that, when every thing is just right, a pretty fair-sized colony may winter on a comparatively small

amount of stores, and be in excellent trim for business in the spring. Notwithstanding this, however, I would rather have a colony of bees that weighed 3 lbs., even if it cost 15 lbs. to winter them, than a nucleus of one pound that could be wintered on 5 lbs. of stores. And this starts another question: About how many pounds of stores would be required to winter a pound of bees, on an average? I would suggest 5 lbs. Now, if some of our bee-hives contain 1 lb. of live bees, and others contain 5 lbs., we can readily see how it will take five pounds of stores for one, and 25 for the other. Dadant, Doolittle, and others have hinted at this thing, as you will notice.

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

THE BUSH LIMA BEAN—FURTHER DEVELOPMENTS.

AFTER receiving a sample of Dwarf Carolina beans from Landreth, mentioned on page 119 of our last issue, I wrote at once, asking how low they could sell us a quantity, also asking them if these beans were not exactly the same thing as Henderson's Bush lima bean. Below is their reply:

A. I. Root—Dear Sir:—Henderson's Bush lima bean is not a lima bean at all, but a Carolina bean. We have had it for five years, and never considered it worth more than a three-line paragraph. We never propagated in quantity. Next year, if people want it, we shall be able to supply it.

DAVID LANDRETH & SONS.

Bristol, Penn., Feb. 14, 1889.

Now, it seems to me no more than just and right that the public should have the benefit of the above opinion, from so great a seedsman as Landreth. It is also just and right that Henderson be allowed to reply. I accordingly submitted to him a copy of Landreth's letter, to which he replies:

Mr. Root:—If any of our contemporaries in the trade have said that our "New Bush lima bean" is "not a lima bean at all," then allow me to say that any one making such a statement is either ignorant of botany and of knowledge of the bean tribe, or that he is actuated by motives unworthy of an honorable contemporary.

The "New Bush lima" is simply a dwarf "sport" from the Sieva (sometimes called Sewee), or Carolina lima, which, though smaller, of course, than the large white lima, is just as truly a lima as the large white lima, which is known in botany as *Phaseolus lunatus*, while the variety known as the Sieva, or Carolina lima, is *Phaseolus lunatus* "minor" (smaller).

My knowledge of this vegetable was from a correspondent in Virginia, two years ago, who wrote me that he had a field of three acres, growing for seed. I could hardly credit his description of it, because such a story seemed too good to be true; but I at once started to examine it, and I found on arrival that it was all he claimed for it—a lima, pure and simple, dwarf as the ordinary bush bean, in no way differing in pod or bean from the large White Pole lima, except in size. When I tell you that we are retailing 500 packets a day of the Bush lima bean, and that our sales, wholesale and retail, will probably reach 250,000 packets before the

1st of June, you can well understand what a serious matter it would be to us if "Henderson's new Bush lima bean" were not all we claim it to be.

PETER HENDERSON.

Jersey City Heights, N. J., Feb. 19, 1886.

Although it seems hard to reconcile these two statements from two of the greatest seedsmen in the world, I think perhaps I can help the matter. In Landreth's catalogue, 1889, first page, he gives a photograph of the bean; and I presume that, when he wrote the above letter, he had forgotten that, right under that photograph, it is called "Dwarf Carolina, or Small Lima." From the above it is evident that Landreth decided to call it a small lima bean. Besides, the picture shows a stalk literally loaded down with pods. It is not a picture gotten up for catalogue show, mind you, but it is an absolute photograph of a stalk of beans pulled up by the roots. This photograph shows that the bean in question is certainly enormously productive, just as Peter Henderson says. Now, then, if the flavor is as good as that of the large lima bean, it is certainly worth all the advertising that friend Henderson has given it, even if it is small. My impression is, that Landreth's folks had not given the bean the attention it really deserves. One thing is certain, also, that they have not any amount of seed on hand, for they say, at the close of their letter, that they will be prepared to supply it next year. Up to the present date of writing it seems that Peter Henderson has the only stock to be had, on the face of the earth. Again, on page 24 of Landreth's catalogue, right under mention of the Large Jersey lima, we read:

Carolina, or Sewee.—A small variety of lima, more easy of vegetation, more vigorous in growth, earlier in season, more profitable in pod than the above. Price \$9.00 per bushel; 45 cts. per quart.

Now, observe that the *above* refers to the Large Jersey lima. Well, if this new Dwarf lima bean has all the qualities of the lima, as quoted, and is dwarf besides, it is certainly an acquisition.

I want to call the attention of our readers to the little incident that comes out in the above, where Henderson went at once to see that three-acre field of bush limas. The act is characteristic of the man; and I presume, although he does not tell us about it, that he bought every bean on that three-acre field. Almost if not all were planted last season, and now Peter Henderson is boss of the Bush Lima bean for the world, for all we know, and he ought to be. He deserves it for his energy and enterprise.

Later.—Since writing the above I have had my wife cook three samples of lima beans. The first was California lima beans, such as we sell at 10 cents a quart—dry beans, of course. The second was some King of the Garden limas that were saved last summer because they were too ripe to shell for the market-wagon. The third batch consisted of three 25-cent packages of Henderson's Bush lima beans. The whole family tasted them and their decision agrees with mine: The California lima beans were very good; King of the Garden limas, excellent—almost as good as green limas;

Henderson's Bush lima bean, very little different from ordinary white beans, with the exception that they have a slight lima taste, but not to be compared with the other two. Now, if, in a green state, they are no better than when dry, our good friend Landreth is not so very far out of the way in saying they are not a lima bean at all. But here comes a card from our good friend W. J. Green, of the Ohio Experiment Station:

Friend Root:—I see that you are disappointed in the size of Henderson's dwarf lima bean, and no doubt many others are also. Thorburn has what he calls Kumorle's dwarf lima, the seeds of which are quite large. I know nothing about it, however.

Agrie'l Exp't Sta., Columbus, O. W. J. GREEN.

We have written to Thorburn, and will report in our next.

THAT EARLY YELLOW PUMPKIN.

Mr. Root:—Inclosed find some pumpkin seeds of a yellow pumpkin that is earlier than anything else in the line of pumpkins I have ever seen. They are very sweet and nice, though they are quite small, growing to weigh only about 8 to 12 pounds.

Wabbaseka, Ark.

G. E. LYTLE.

We have got it already, friends—see? And here is another:

My wife sends you some pumpkin seeds called "Garden" pumpkin, as per Feb. 15th GLEANINGS. They are "boss," small, but grow quickly.

Mosiertown, Pa., Feb. 18, 1889. GEO. SPITLER.

There, friends, do you see how readily we can get almost any thing we want by submitting it to the combined wisdom and experience of the readers of GLEANINGS? and here is still another friend with his offering:

A. I. Root:—We notice you want an early variety of pumpkins. We have an *extra-early* variety, but it is in a *tin can*. Now, our people here never think of *cooking* a pumpkin, as they think our canned pumpkin is an improvement on what they can *cook*; besides it is ready for immediate use. Will not this answer?

D. CUMMINS.

Conneaut, O., Feb. 22, 1889.

You see, friend Cummins is in the canning business, and his early pumpkin is certainly early enough for anybody, for it is always ready for use, as we can testify from personal experience, winter and summer; and a whole can full, can and all, can be sold at retail for only 10 cts. If you want a single can for sample, when you are ordering goods of us just mention it and we will put one in at the above prices. If you want them by the case of two dozen each, I presume friend Cummins will be glad to fill your orders.

FRIEND MARCH'S CABBAGE SEED—ANOTHER REPORT.

The trial packet of March's seed we planted last season gave the best of satisfaction. It was fully as early as Etampes, and a better header. (Wife says the above is not strong enough; the Wakefield seed was sown two weeks later than Etampes, and produced the first heads fit for use.) S. P. YODER.

East Lewistown, O., Feb. 21, 1889.

I wish to add to the above, that we have for many years tested almost every new

cabbage that has been recommended as being earlier than the Wakefield, to be found in our catalogues, and so far we have not found one of them that made a good solid head. Last season we planted two long rows of Johnson & Stokes' Wonderful; but our customers would not have them at any price when they could get Jersey Wakefield, as they were soft and loose; and I presume we lost a couple of dollars that would have been saved had we planted Jersey Wakefield. I am still going to keep on testing early cabbage, but I shall not put out over a dozen plants of any kind again until I find something not only earlier, but as hard and solid as the Wakefield.

TRAINING TOMATOES ON BEAN-POLES.

Set the plants three feet apart each way, and rather deep in the ground; in fact, as far down as the plant will admit, as the less plant above the surface at the start, the shorter and more bulky the vine will be, which is a very great advantage when the fruit is large and abundant. Very tall and leggy plants may be set out by making the hole trough-like, as you would to set out grapevines, and cover up the leggy part of the plant, and leave only a small part of the top above ground, as the stem of the plant will send out roots all the length that is under ground. The next move will be to drive down firmly by each plant a strong pole or stick, not less than six feet above ground—hoop-poles or sticks from lumber yards, such as are used for "sticking" plank will do well. When the plant is high enough to need tying to the stake it will need pruning, and, most likely, before. Every sucker must be taken off then, not one being allowed to remain, and the vine will, of course, consist of one single stalk, and must be kept so, to give large perfect fruit, and late into the fall. The tying to the stake must not be neglected after being begun, or the vine will fall over of its own weight, and likely break off. In pruning do not take off any of the leaves, as they are needed to shade the fruit and ground, and will grow just right to do it, and are, in fact, the life of the plant. Some years we are much troubled with cut-worms; and to go out some fine morning and find about every third plant lying over on its side, with no connection with mother Earth, is very exasperating. I would suggest, as a remedy, to wrap the stem of the plant loosely with a small piece of tissue paper, always allowing the grain of the paper to run up and down the plant instead of around it, so if you forget to remove it after the worms have disappeared, the growing of the plant, with the aid of a shower, will burst the paper. The fruit should be gathered before it gets too ripe, especially if it is to be shipped to market; and when it is gathered, put it in the shade instead of the sun, as is frequently done. Seed should be saved from the earliest and best specimens, dried on paper, and the variety and date put on the paper at the time. J. S. REESE.

Winchester, Ky., Feb. 4, 1889.

Friend R., I think very likely your plan would answer tiptop. I certainly think it would be a great gain indeed to be able to get our tomatoes away up above the ground, where they would not get spattered with muddy soil during heavy rains, and I do not know but that this one thing alone would pay for the expense of poles, and tying up.

OUR HOMES.

NOTES OF TRAVEL.

If thou turn away thy foot from the Sabbath, from doing thy pleasure on my holy day; and call the Sabbath a delight, the holy of the LORD, honorable; and shalt honor him, not doing thine own ways, nor finding thine own pleasure, nor speaking thine own words: Then shalt thou delight thyself in the LORD; and I will cause thee to ride upon the high places of the earth, and feed thee with the heritage of Jacob thy father: for the mouth of the LORD hath spoken it.—ISAIAH, 58: 13, 14.

OUR next adventure was crossing the main range of the Rocky Mountains. This trip was by daylight; and as the road does not follow any stream of water it was much more romantic. In order to get up hill, the track runs around

and up, partly on one mountain and then on another, and oftentimes it runs at different heights on the same hill. The conductor pointed to one place during the ascent, where the track could be plainly seen in four different places—the uppermost, clear up in the clouds. As we approached the summit we were greatly annoyed in our view of the valley by the snow-sheds, and also by the snow-storms, until we got above the clouds. As we neared the summit still more, the coal smoke left by a train just before us became very unpleasant in the snow-sheds; but when we finally stopped on the extreme summit, at Marshall Pass, nearly two miles above sea-level, I began to wish very anxiously to have them start down again. The rarity of the atmosphere made me pant for breath, as if I had been climbing the mountain, when I just sat there in my seat and had not walked a step. The descent was much pleasanter, for the sun shone; and when we got down in the valley it was very fair summer weather, while on the mountains it snowed and blew, and was terribly cold.

After we reached the summit of the mountain, of course we did not need the two locomotives that had pulled us up, therefore one of them started on ahead in order to be at the foot of the mountain when the next train came along, going in an opposite direction. This solitary locomotive, as it wound its way through the rocky cliffs, and threaded its way down below, was a most interesting sight to me, for it indicated more plainly the curves in and out. I can not tell it. My gift of language is not equal to the occasion; but I can come pretty near it by quoting an extract from the same book I have quoted from before—"The the Continent." You will notice the author was going in an opposite direction from myself.

To attain this height, the road has to twist and wriggle in the most confusing way, going three or four miles, sometimes, to make fifty rods; but all the time it gains ground upward, over some startling bridges, along the crest of huge fillings, through miniature canyons blasted out of rock or shoveled through gravel, and always up slopes whose steepness it needs no practiced eye to appreciate. To say that the road crosses a pass in the Rocky Mountains 10,820 feet in height is enough to astonish the conservative engineers who have never seen this audacious line; but you can magnify their amazement when you tell them that some of the grades are 220 feet to the mile.

We have just passed through Grand Canyon, on the Arkansas River. It is much like Black Canyon, only the cliffs are still higher. Some of them that hang right over the cars as they thunder along, I do believe are fully three-fourths of a mile to the top. Many of these great leaning cliffs are ap-

THE ROYAL GORGE.

Crest of that the direction

parently of rocks so loose and rotten that a little jar might set them tumbling. Many of them greatly resemble a certain kind of rotten wood, both in appearance and color.

There is one special point in Grand Canyon where the rocks rise higher, and the fissure where the river and the railroad run is still narrower, that I wish to mention. It is what is called the Royal Gorge, and the train stops here for a few moments to allow the passengers to get out and look around. The Denver & Rio Grande Railroad Co. have kindly loaned me a picture of it (see preceding page).

At this point we seemed to be so far in the depths of the earth that one is tempted to think we are soon to be at the end of the road. In fact, as we look out in advance of the train, and the short curves make it possible to see not only the locomotive for the greater part of the way, but the train itself, we are tempted to think we have run into a place where there is no outlet. Very likely, however, you have learned to have faith in the locomotive, and to feel safe wherever it plunges ahead.

Oh, yes! here is an outlet; but it is so narrow you begin to wonder how both the river and the railroad can find room. Well, this is exactly the problem that confronted the engineers when they laid out the road. There is not room for both; for when the river rises it fills the whole opening between the cliffs. Necessity here proves to be the mother of invention, and the track is placed on a sort of bridge, one side of the bridge being let into the rocky cliff—the other side, or, perhaps, more properly speaking, the ends of the railroad ties, resting on a timber that is suspended under their ends, running parallel with the iron rails. The river rushes along right under this timber—in fact, it refuses to be contracted even one inch. It must have *all* the space between the rocky barriers on either side. How, then, shall that timber that holds the ties over the water be supported? The picture will show you how they did it. Braces of great timbers, something like the letter A, span the river. One end is set in the rocks of the cliff at one side, and the other end in the other; and from where the timbers meet, great iron rods reach down and hold the track securely, with one edge over the boiling and seething torrent. I got off the train and stood on the track near those timber braces. I tipped my head back and looked up, up, up, until the rocks seemed on a level with the great birds as they swung lazily in the sky. I stared with open mouth until my neck ached, and then looked on the opposite side. There it was just the same. Look at some object just three-fourths of a mile distant from you, and then picture to yourself a rocky precipice straight up that distance. When tired again, I glanced at my twelve fellow-passengers, and then I looked at the railway train and the locomotive. The author of "The Crest of the Continent" says, after viewing the above he looked at his fellow-men, at the locomotive, and then concluded: "Of all natural curiosities, *man* is the most curious—yes, more marvelous than even the Grand Canyon itself." Before dismissing Grand Canyon I want to make another quotation from the above writer.

This is the Royal Gorge! But how faintly I tell it—how inexpressible are the wonders of plutonic

force it commemorates! how magnificent the pose and self-sustained majesty of its walls! how stupendous the height as we look up, the depth if we were to gaze timidly down! how splendid the massive shadows at the base of the interlocking headlands—the glint of sunlight on the upper rim and high polish of the crowning points! One must catch it all as an impression on the retina of his mind's eye,—must memorize it instantly and ponder it afterward. It is ineffable, but the thought of it remains through years and years a legacy of vivid recollection and delight, and you never cease to be proud that you have seen it.

At Pueblo, Colorado, I am again surprised to find a summer temperature, and to be told they have only five or six weeks of winter.

It is Saturday night, and the question confronts me, "What about Sunday?" My fellow-travelers have announced their determination of traveling right along, so as to get home. In my pocket is a letter from my wife, telling me that they expected me more than a week ago; also that she could not take Huber to church any more; for when he looks over to where papa usually sits, at the right of the empty seat, he bursts out sobbing, and has to be taken home. Dear little Huber! what would I give to get hold of him to-night? I am afraid I am a little homesick. The temptation is strong to rush right on home. But, how shall I feel all the long day, encouraging, by my presence, Sunday travel, or, rather, *no Sunday* at all? It is exactly like buying the memorandum-book last Sunday. By my act I should be saying to the great busy world, "You are all right as *you are*." Four Sundays have passed since I left home, and they have been glorious ones. Shall I lose courage on the fifth? God help me to do right. To be ready to keep the Sabbath "decently and in order," I should stop certainly by 6 o'clock, for I want to *get ready* for Sunday, and make a short call on the pastor of the church where I expect to attend. I believe my deaf friend was about right when he said he thought we ought to even *black our shoes* Saturday night in order to keep the Sabbath in the best sense of the word. Once more I am about to go among entire strangers. Satan says, "Nobody will know you or care for you here surely," but, with a prayer that the spirit of the Master may go with me and before me, I make my decision. I hardly need tell you that my heart felt lighter as soon as I had decided on this step.

During the past week I have already figured up about where I should be when Saturday night came, and I have selected a little town at the base of Pike's Peak (much talked of by the gold-hunters in 1859), called Manitou Springs, as my resting-place during the Sabbath. I selected this spot on account of certain attractions in the way of natural scenery beside the great mountain; and the conductor had already told me that we should be there about six o'clock. It was now about four o'clock, but no mountains were in sight, except a clump of hills off toward the northwest. The tallest of these, I had decided in my own mind, was probably Pike's Peak. This little group of mountains was probably forty or fifty miles away; but at the rapid rate at which we are going we should probably reach them in

two hours. Darkness came upon us, and I could see no more. Shall I tell you how it turned out? Well, I asked a young man if he could direct me to a quiet temperance hotel, where the charges were moderate. I also made some inquiries about Pike's Peak; for by the light of the stars I could see that the town was surrounded by mountains, except on one side, where the train ran in. A hotel was pointed out to me, and my informant also asked me if I could see the snow-capped mountain just back of the town. I told him I did.

"Well," said he, "that mountain, with its top covered with snow, is Pike's Peak."

"What! that great hill up close to the buildings yonder?"

"Yes, sir, that great hill up close to the buildings. But you may be surprised, however, to learn that it is not so *very* close, after all, for it is fully *thirteen* miles away."

Could it be possible? I gazed at the hills so long, wondering how it was possible that the mountain could be thirteen miles away, when it seemed almost overhanging the town, that I suppose I forgot which way he pointed when he told me to go to the hotel where I saw a light. Of course, I made a blunder, and got the wrong place; but, dear friends, did it never occur to you that, when one is seeking the guidance of his heavenly Father, even his blunders seem to be looked after? The place where I did go was a little hotel on the hillside, called Mountain View. A tidy, trim little woman, with a pleasant Scotch accent, informed me that their rates were only \$1.25 a day. She told me, further, that there was a Congregational church in the place, and that it was close beside us; yes, the pastor lived near by too; in fact, he was almost their next-door neighbor. I told her that I had a severe headache, and did not care for supper, any more than a cup of tea and some toast; but she took so much pains to make every thing pleasant, and to look after my comforts and wants, that I had forgotten my homesickness a good deal, even before I went over to call on the pastor of the little stone church. When I told them the circumstances, he and his good wife, and even the children too, treated me with as much consideration as if I were a member of their family. I felt too tired, however, to talk much. I told them I came principally to get some lesson-helps, to prepare myself for the Sunday-school on the morrow. The pastor's wife then said she had been wondering how she should find somebody to take her place as teacher of the Sabbath-school on the following day, as she was prevented from attending to it by other duties. I promised her to take charge of the class as well as I could, if I were not too hoarse to speak. They then both advised that I go back to the hotel and go to bed; and the good pastor added that, if I were not better in the morning, they would make it their business to take care of me until I was better. As I lay down to rest, I really feared that I was going to be sick; but I felt happy to think of the friendly hands I had fallen into.

As the morning sun poured into my pret-

ty little bedroom, my first thought was a feeling of thankfulness that I felt so well. Right in sight was that old white mountain, Pike's Peak, of the night before. An excellent breakfast soon made me feel quite well. The three or four young men who were boarders there not only enlightened me in regard to Pike's Peak, but also Grand Cavern on the mountain-side that, in some respects, rivaled Mammoth Cave; Rainbow Falls, the Cave of the Winds, the wonderful effervescing springs, and last, but not least, that strange product of nature, the Garden of the Gods, as it is called. One of them said that he was so busy during the week, he had not had time to see these celebrated places; but he thought he would go over during that bright sunshiny day, and he indirectly intimated that he would be glad to have me accompany him. I told the boys that I was very much interested in these strange things, but I did not believe in visiting such places very much on Sunday, but that on *Monday* I should be very glad of any instruction. As we went back to the sitting-room, one of my new friends asked me to look out of the window at Pike's Peak. I did so.

"Well, do you see the snow rolling in great drifts over the peak, and whirling in the wind?"

As soon as he mentioned it, I saw it distinctly, and uttered an exclamation of surprise—especially so as, down in the valley where we were, it was a comparatively warm spring morning. He further informed me that snow is blowing and whirling almost every day in the year away up on the summit of Pike's Peak.

While the boys went their several ways I sat down in the little sitting-room to study, and to prepare myself to teach my class. I not only read all the lesson-helps, but I took the Bible and read the whole history of Samson, from beginning to end. When the pretty little church built of mountain granite was opened, I was one of the first to enter. Did you ever know, dear reader, that a peculiar blessing seems to rest on those who gather *first* in God's holy house? I confess now that it has not been my custom by any means to be among the *first* at home; but during my vacation of four or five weeks, I have, somehow or other, been in a hurry to get to church or Sunday-school. On this Sabbath morning I felt particularly happy. Bright little faces soon followed me, and gathered into the Sunday-school. In Manitou they have Sunday-school before preaching. Pretty soon a little one, just about Huber's size, and remarkably like him, came up the aisle and made straight for me, taking hold of my arm, as if it always knew me. The act almost startled me; but it awoke in my heart a fervent "God bless the child!" and while the superintendent was speaking as the school opened, this same little one turned back to some boys and communicated the astounding piece of intelligence that she (I found out after that it was a little girl) had just had her *hair cut*. This piece of information was so extremely funny that she followed it up by giggling out loud. The superintendent

very gravely took her by the hand and led her up by his side, and then made her sit down by the steps of the pulpit. It seemed to me a little severe, and I was afraid she was going to cry; but she only hung down her head; and pretty soon, when his attention was taken up by the work of the school she edged off slightly, so that, when he looked for her again, she was missing. Now, this was a mere trifle, dear reader; but somehow or other it brought vividly before my mind the task that the Sunday-school teachers and superintendents have upon their shoulders—the leading of these precious little souls to Christ Jesus. And then burst upon me, as never before, the words, “Suffer the little children to come unto me, and forbid them not.”

After the school was over, the little blue-eyed chick came up to me again, and the superintendent came at the same time. It was *his* little girl. It seemed to me as if I loved them both—father and child—as though they had been near relatives all my life. I told her about my little Huber at home; then I asked her some questions.

“Will you tell me your name, my little friend?”

The only reply I got, however, was, “I had my hair cut yesterday;” and then she indulged in her childish fun again.

“But won’t you tell me how old you are?”

“Next May,” was all the reply I could get. Then her father asked me how I got on with my class. I looked up into his kindly face, but I did not dare to tell him the whole truth. Had I done so I should have said it was one of the happiest half-hours of my life. I decided to say only, that, for my part, I had enjoyed it exceedingly. One of the members of the class—a bright, intelligent lady, who had strengthened me by her kind and wise words, added:

“And I am glad to say, Mr. Superintendent, that the class have enjoyed it also—at least, I have enjoyed it very much.”

What a nice lot of men and women were in that class! Was it possible that Manitou contained more good people than all the rest of the world, or was it only the peace of Christ Jesus, and that his great love had found a lodging-place in my heart that Sunday morning, that had made me feel like loving every thing and everybody?

There was another little circumstance that made that morning service so bright and glorious. Right back of the pulpit, in beautiful letters on the wall, were the following words:

“Let the words of my mouth, and the meditations of my heart, be acceptable in thy sight, O Lord, my strength and my redeemer.”

When those words first burst on my view, it seemed that it was the most grand and glorious text that the Bible ever gave to poor humanity; and the oftener I read the words, the brighter they shone forth, as a beautiful prayer for weak and sinful people like myself. I thought of my wavering decision of the night before; but I can not tell you how I thanked God that I had *not* chosen to travel on Sunday. During my stay I had had several arguments, and some pretty serious talks, with avowed infidels and

skeptics; and the thought came into my mind, Is there an individual in the whole wide world who can honestly raise the slightest objection, or offer a single breath of criticism, on that wonderful prayer?

I can’t tell you the *wide* difference between having the prospect before *me* of Sunday travel, contrasted with a day among Christian worshipers. Do you say it is an easy matter to make *me* happy? My friend, it is an easy matter to make *everybody* happy, when they are in the path of duty. A thrill of peace and joy poured down into my soul so like that of my first experience, when I dropped the whole world for Christ Jesus, that it was hard for me to keep the tears back. What a bright and pretty gathering of boys and girls, and what a class full of intelligent and refined gentlemen and ladies were in my class. My heart went out in love to every one of them. I read the text again and again, dwelling longingly on the different shades of meaning. Did David ever long for the presence of God in his heart as *I* have longed, and did he ever have cause to pray as *I* have prayed, that his inmost thoughts might be acceptable to God? How exactly it fits with my temptation and triumph of yesterday! To-morrow I am going to visit, and describe to you some of the natural curiosities about here; but, dear friends, there is nothing in this whole universe to be compared with the riches—the *boundless* and *inexhaustible* riches of the simple words of the text I have quoted.

RECENT DEVELOPMENTS

CONDUCTED BY ERNEST R. ROOT.

THE DOVETAILED HIVE.

THE tendency of the times is more and more toward simplicity. The most practical honey-producers—those who own colonies by the hundreds and not by the tens, incline toward (if they do not already use) cheap, substantial, and simple hives and fixtures. Indeed, the price of honey is such that they can not afford expensive and complicated arrangements. In the past few months our foreman (Mr. J. S. Warner), Mr. Calvert, and your humble servant, have been considering the question of a still simpler and still cheaper hive than the Simplicity, though not necessarily cheaper in quality. Dr. C. C. Miller’s advice and assistance have been freely sought through correspondence. After a good deal of arguing and discussion, and a careful study of the needs of the times, we have at last brought out what we shall call the Dovetailed hive, a cut of which we append below.

As the name indicates, its distinctive feature is the dovetailed corners. To do this work we have recently put in some expensive machinery. Almost any child can drive such a hive together. If each of the dovetailed ends be dipped into paint before driving them together, and then cross-nailed, you have a joint that, for strength, can hardly be surpassed. No iron gauge-frames nor any thing of the sort is necessary. The hive proper is simply an eight-frame hive

with square edges (that is, unbeveled), having a plain bottom-board cleated at each end; a plain cover, likewise cleated, with this difference, that the cleats have a longitudinal groove $\frac{1}{8}$ inch wide, and $\frac{1}{8}$ inch deep, to admit the ends of the cover-board, as shown in the cut. The front of the bottom-board is cut out so as to permit contracting the entrance in the same manner as is done with the Simplicity hive with the alighting-board. The brood-chamber may be used for an upper story for extracting if desired. Each body is of the width of an eight-frame hive, and deeper than a Simplicity frame by a bee-space, making a total depth of exactly $9\frac{1}{2}$ inches. The frame-rabbets are simply plain wood bearings (without tin rabbets), which bring the top-bar of the frame flush with the top edge of the hive. "Take care, there!" you will say; "you have made a mistake—there should be a bee-space above the frames in the hive." Let me explain. In order that the brood-chamber may be used interchangeably as a brood-chamber proper and as an extracting super, you will see, upon a moment's reflection, that the body should be deeper by a bee-space than the extracting-frame. If a bee-space is left on top, and a bee-space below, when one

THE DOVETAILED HIVE.

body is put on another there will be a distance of $\frac{1}{8}$ inch, calling a bee-space $\frac{5}{16}$ of an inch. How, then, do we provide for a bee-space above the frames? Use a honey-board, to be sure, bee-spaced on both sides. Judging from reports that have come in, and the statements of our most extensive honey-producers, and from our own experience, we feel sure that the honey-board will save not only time but patience, and in the present state of our knowledge of apiculture it is in reality an indispensable fixture to the hive; therefore the honey-board of the Dovetailed hive is to have a bee-space $\frac{5}{16}$ inch above and below the slats or zinc, as the case may be.

We now come to the surplus apartments. In the present state of progress in hives and supers, you and I scarcely know what kind of a surplus arrangement we may be using or advocating, say two years hence. Dr. Miller has made a similar statement in print, I think, in his "Year Among the Bees." In view of this fact, were it not well, since we are making a new hive, to construct a super for it that can, with no very great difficulty, be adapted either to a

T super proper or to a wide-frame arrangement? If this year we adopt the T super, possibly next year we shall find it to our advantage and to our interest to change to a wide-frame arrangement, if we can do so at no very great expense. Well, a T super should be $4\frac{1}{2}$ inches deep—that is, $\frac{3}{8}$ inch deeper than the $4\frac{1}{4}$ section, so as to leave, after proper shrinkage, $\frac{5}{16}$ bee-space above the sections. With this fact in view, how shall we adapt it to a wide-frame arrangement? We did it this way. The engraving below shows the section-holders, as we shall call them, to distinguish them from the wide frames proper.

SECTION-HOLDERS FOR THE DOVETAILED SUPER.

You will notice there are no top-bars, the reason of which will be made obvious presently. The end-bars are $\frac{1}{8}$ inch thick, and exactly $4\frac{1}{4}$ inches long, and $1\frac{1}{8}$ inches wide. The bottom-bars have openings to correspond with the openings in $1\frac{1}{8}$ sections, and are exactly $\frac{3}{8}$ inch thick. Our super-shell, you will remember, is $4\frac{1}{2}$ inches deep. Into this we set these section-holders, the ends of which are supported by a strip of tin. The sections are $4\frac{1}{4}$ inches deep; adding to this $\frac{3}{8}$ for the bottom-bar of the section-holder we have $4\frac{7}{8}$. This figure, subtracted from $4\frac{1}{2}$ (the total depth of the super) will leave $\frac{3}{8}$ bee-space above the sections. This bee-space, I grant, is rather scant; but there are those who claim that if there is just barely enough room for bees to crawl through, they will not propolize. At any rate, we deemed it better to leave the top of the sections unprotected by a top-bar than to protect them. One of my greatest objections to the wide frame proper is that propolis is deposited between the top-bar of the wide frame and the top of the sections, for the reason that the sections sag away from the top-bar; but the amount of propolis is reduced to a minimum between the bottom of the sections and the bottom-bar, for the reason that gravity draws the section close in contact with the support below. Now, then, if we should prefer to use T supers, we shall have to close the space up at the two ends, with a board $\frac{1}{8}$ inch thick—the space occupied by the end-bars of the section-holders. The T tins may then be put in, and the sections be placed in the super, and an ordinary T super is the result. You may urge, why not make the T super shorter? For a reason I will not attempt to explain here, I will say this can not be done very easily, so that the adoption of the $\frac{1}{8}$ -inch board seems to be the only solution to us thus far.

WIDE FRAMES VERSUS SECTION-HOLDERS.

The facility with which wide frames or similar arrangements can be shifted from outside to center, and vice versa, is a strong argument in their favor. While our section-holders possess this feature, unlike wide frames (in the absence of the top-bar) they can be filled and emptied easily. While I do not wish to do any thing to discourage any one from taking hold of the justly popular T super, I wish simply to say that our section-holders are better adapted to the Dovetailed hive.

Our dovetailed supers can be used for the half-depth bodies, if desired; and one of them placed upon the other will take extracting frames when circumstances require it—for instance, an unexpected rush of honey when the bee-keeper is unprepared with extra bodies. Each of these super-shells has the ends rabbeted for the purpose; and right here I want to say that this rabbet affords the nicest kinds of finger room to grasp the section-holders. The fingers can be let down into the rabbet, and grasp the upper edge of any individual holder, so that you will see this rabbet may be made to serve a double purpose.

IS THIS HIVE NEW OR OLD?

This hive is not new. In appearance it is similar to the old-style eight-frame Heddon-Langstroth. As we paid Mr. Heddon, some three or four years ago, \$100 for using any or all the features of this particular hive that we thought proper (none of which we have used hitherto until now), we are sure that he will not accuse us of copying without credit, or without a just recompense. The feature of dovetailing is, of course, not new, but it has quite recently been applied on a large scale to hives, and that by some of our good friends in Australia, and by our friend Mr. Danzenbaker, of Claymont, Del.

I want to say right here, that, although Dr. Miller has helped us not a little by way of suggestions, it is not just exactly his ideal hive. With the T super, pure and simple, one that would not require taking up the space with loose boards, and with a reversible bottom-board, it would be just his ideal, exactly; but he agrees that, for the masses, the hive as we propose making it is about right, although his individual needs would require one or two slight changes.

That this hive is considerably cheaper than the Simplicity or any of its combinations, you will see by comparing prices found in our Special Notices. In most cases it will be found from 25 to 33 per cent cheaper.

PRICE LISTS RECEIVED.

S. L. Watkins, Placerville, Cal., sends us a one-page list of honey and Carniolan bees.

J. M. Hanching, Spring, Ill., sends us a nice 12-page list of apianian supplies.

The W. T. Falconer Mfg. Co., Jamestown, N. Y., send us quite a complete list containing a list of apianian supplies.

Falmere, New York, sends us his list of bees, poultry, seeds, and pigs.

H. G. Frame, North Manchester, Ind., sends us a 4 page price list of queens and bees.

Hammer & Lathrop, Lewistown, Ohio, have just had printed at this office a 16-page list of bees, queens, etc.

We are now printing over Foster's annual list of supplies. It will be ready for delivery by the time this journal is read. The address is Mr. Vernon, Ia.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, OHIO.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, MAR. 1, 1889.

Let the words of my mouth, and the meditation of my heart, be acceptable in thy sight, O Lord, my strength and my redeemer. PSALM 19:14.

GOOD SUBJECTS TO WRITE ABOUT.

We are glad to notice the evident disposition of our correspondents to review and reconsider the contents of "Our Question-Box" after they have been once submitted. The questions are selected and worded with great care, and are good subjects to write about.

HOW TO RAISE SWEET-POTATO PLANTS.

In answer to my request in the last issue, we have received up to this date 30 excellent articles on the subject, and I do not know but I shall put them all together in a little pamphlet. We will try to have it before our readers in some shape before time to commence operations. Please do not send any more.

GREAT IS TRUTH, AND WILL PREVAIL.

A FEW months ago I was saddened and somewhat discouraged because there seemed to be an attempt on the part of quite a good many men to revive patents on bee-hives; and even as good a man as our jovial friend D. A. Jones thought best to offer rights for sale. I am, however, much refreshed to notice the following in the *Canadian Bee Journal* of Jan. 23:

I object to patents on bee-hives, and am pleased to say that the simplest and most practical hives of the present day are unpatented, so that any one is at liberty to make for himself almost any hive which takes his fancy and suits his ideas of practicability.

OMITTING TO GIVE FULL ADDRESSES WHEN RENOVING.

RENEWALS and new names are coming in at a rapid rate. This, of course, is gratifying; but some of our good friends, on renewing, simply sign their names, without giving either postoffice or State. Please bear in mind that our subscription-list is arranged alphabetically according to postoffices; and unless we have your full name and address we can not very well renew your name without going to a great amount of trouble, and even then we sometimes have to give it up as a bad job. If we happen to have previous correspondence, or if the name happens to be on our ledgers, we can then find out what the postoffice is. Our subscription clerk informs us that, at the rate renewals are now coming in, there is about one a day which does not contain the proper address. A day or two ago we received a letter from a man, asking us to renew his subscription. He not only failed to give his postoffice and State, but he failed to give his initials. The postmark on the envelope showed that his State was Illinois. Knowing this, our clerk looked at our long list of Illinois subscribers,

and succeeded in finding the name. As a general rule we can not afford to do this, and consequently have to wait until the careless individual complains. A very little care on your part saves us a large amount of trouble.

FALSE STATEMENT IN REGARD TO THE ADULTERATION OF HONEY. SEE PAGE 163.

The clipping, entitled "Bogus Honey," has been sent us again. It was taken out of the *Albia* (Ia.) *Union*, and they credit it to the *Oskaloosa Herald*. If any of our readers live near these papers, or take them, will they help us by writing to the editors and inclose this number marked? We will furnish them just as many copies as they need.

THE PREMIUM BUSH LIMA BEAN FOR SUBSCRIBING AHEAD.

ANY one who pays up his subscription to the present date, or ahead of the present date, and then sends us another dollar for another year ahead, can have a package of Henderson's new Bush lima beans; and any one who takes *Gleanings*, no matter how or under what circumstances, can have a package of the *Ignotum* tomato seed on application. We give the above in answer to many inquiries.

THE AMERICAN BEE JOURNAL AND ITS BIOGRAPHY OF A. I. ROOT.

In the *American Bee Journal* for Feb. 23, page 117, appears a fine *Ives* engraving of the editor of *GLEANINGS*, together with a biographical sketch. We extend our hearty thanks to Bro. Newman, not only for the excellent engraving, but for the very, very kind words said of us at the end of the sketch, by himself. In speaking of our relations in the past, he says: "Mistakes have been made; but with both parties anxious only to be right, they have been readily adjusted." The italics are ours. We most heartily indorse these sentiments.

HOW TO MAKE HENS LAY.

FOR two winters past we have been starting our Brahmas to laying by feeding them cooked beans—the beans being the culls from those picked over for our market-wagon. There is no doubt about it. They will start them to laying within 48 hours. Well, a few days ago we had a surplus of hulled corn (boiled corn), and quite a lot of it was given to the Brahmas. We had been getting three eggs a day; but the day after they had the boiled corn we received seven eggs. Now, then, shall we say that cooked corn is as good as cooked beans, or even better? I think not. Shall we say, then, that cooked grain starts them to laying? Not necessarily. I think it is just this: A change of diet at just the right time. A good feed of raw cabbage, when they have not had any for some time, will at once set several hens to laying that had not been laying. Lettuce produces the same result; and for hot weather I think it is even better than cabbage.

APICULTURE IN SPAIN.

WITH the beginning of the year, friend Andreu, editor of the *Revista Apicola*, published in Mahon, a city in the Balearic Islands, off the east coast of Spain, has enlarged his neat little journal from 8 pages to 16, and prints it on nice calendered paper, and also puts on a cover. Friend Andreu is fully abreast with the spirit of the age, which seems in strange contrast with the conservative spirit of the Spaniards in general. Being free from such winters as we have here, although in the same latitude,

the question of wintering seems to cut no figure with them. The kindly editor not only writes Spanish, of course, but his letters in English show him to be even more familiar with our language than the majority of those who have always used it—see p. 516, 1888. The advent of his paper is always a source of pleasure, for it indicates the rapid spread of modern ideas of apiculture in that land of romance and song. By the way, it was here that, in 1796,

Old Ironsides at anchor lay.

In the harbor of Mahon:

A dead calm rested on the bay,

And the winds to sleep had gone.

When little Jack, the captain's son,

With gallant hardihood,

Climbed shroud and spar,

And then upon the main-truck rose and stood.

SHALL WE FOLLOW OUR SPIRITUAL LEADERS?

SEVERAL of the good friends of *GLEANINGS* have entered a mild protest to the position I take on page 101, Feb. 1. Now, there is not room, even if it were advisable, to discuss doctrinal points in theology in the pages of *GLEANINGS*. Such matters had much better be left, in my opinion, to the pastors of our respective churches, who have had a theological training and a theological education. Shall a member of a church confer with his pastor and get his advice on these points, or shall he go off on his own hook? It seems to me, dear friends, the man who leaves his church and pastor because they can not agree or think alike on all points is much like the man who leaves his wife because of little differences. If he gets a divorce and takes another wife, he has ten times more trouble than with his first one. If you think I am mistaken in the matter, see how such things turn out in your own neighborhood. By their fruits ye shall know them. First and foremost, and above all things, read your Bible carefully and prayerfully, then consult your pastor.

WANTED.

THE principal thing that seems to be wanted just now is some sort of a scheme to induce those who have much money and few wants to hand over some of the surplus to the rest of us who have many wants and "few" money. Now, I am not getting toward anarchy, for you know that is not like me. I am simply looking for plans to bring it about in a legitimate way. Raising lettuce and strawberries in greenhouses for rich folks to adorn their tables in the winter time is one of the ways. Gilt-edged butter comes in the same line. My brother-in-law took me to a restaurant in Cincinnati that is celebrated for the excellence of its steaks. The waiter gave each of us a great slice that might make a small man feel bashful until he had taken a taste of it. Why, my friends, it was away ahead of roast turkey or any thing in that line. This restaurant always keeps just that kind, and they have a host of customers among people who are not only willing but glad to pay an extra price to be sure of getting this extra corn-fed beef every time. At Baggs's Hotel, in Utica, N. Y., where each meal costs a dollar, every thing was gilt-edged. If you called for a baked potato it was a great whopper, roasted in the ashes, as in the good old times, and the quality of the potato was so choice that all you had to do was to break it in two, rap on the charred outside, and the smoking contents rattled out dry and fluffy. Twice in my life have I tasted such baked potatoes. The first time was more than forty years

ago, when grandmother used to bake Lady Fingers in the ashes on the hearth of the wide old fireplace. Well, the experiment stations say the sole trouble with the Lady Finger nowadays is, that it is an extremely poor yielder. And now you can see what it is that I want. I want a potato as good as the old-fashioned Lady Finger, that *yields well*. Can any of the brethren furnish it? If so, send me one or two by mail, and I will have Mrs. Root roast them in the ashes; and if they even come pretty near the Lady Finger we will give you a free advertisement of your seed. Surely somebody ought to have this potato. A catalogue is just at hand, offering 700 different varieties of potatoes. It would be a little sad if none of the 700 could come up to the Lady Finger as a baker.

We have at this date 8477 subscribers.

SPECIAL NOTICES.

We now have Dadant's Langstroth Revised, and can send them out by return mail. Price \$2.00. By freight or express, 15 cts. less.

WANTED—SPIDER-PLANT SEED.

Mail us a sample, tell us how much you have, and we will write you what we can pay for it. We want seed of last season's raising.

ALSIKE CLOVER.

We have a nice stock of alsike clover seed, to fill orders on short notice. I believe it is the nicest seed we ever had for sale. The secret is, we have had a good many samples to choose from, and selected only the best. Our prices: \$2.25 per peck; \$4.40 per half-bushel; \$8.50 per bushel. In lots of 5 bushels, \$8.00 per bushel.

THE IGNOTUM TOMATO SEED.

Since my last mention of it, we have given away about 1000 more packages, making 2000 in all. And now the friends begin again to say, "Send me a package if it is not all gone." Why, bless your hearts, there are at least 3000 more packages to be given to subscribers of GLEANINGS. Just say, "Send us a package of that tomato seed," and do not put in any thing about its being gone.

FOR SALE, ENGINE LATHE AT ONE-HALF PRICE.

It swings 15 inches over bed; takes 40-inches between centers; has both foot-power and counter-shaft; is back-gearred, screw-feed, and screw-cutting; cost \$150.00. Will clean up, paint, and pack for shipment, for \$75.00. It is now in use in our machine-room, and we would not think of selling it except that our work now demands a heavier and larger tool. This is undoubtedly a good opportunity for some one to secure a valuable tool cheap.

THE CHARTIER RADISH.

A great trade has sprung up on this favorite radish, and we have bought such large quantities of the seed of the originator, Wm. C. Beckett, that we can give the following low prices: 5 cts. per oz.; 10 cts. per $\frac{1}{4}$ lb.; 35 cts. per lb. If wanted by mail, add at the rate of 3 cts. per $\frac{1}{4}$ lb., or 9 cts. per lb., for postage and packing. See the latest issue of our seed catalogue, giving reductions on many kinds of staple seeds, issued Feb. 15—mailed free on application.

"KING OF THE GARDEN" LIMA BEANS.

Since my test (mentioned in another column) of dry lima beans, I have concluded that we did not quite appreciate the King of the Garden last summer. Their immense size makes it much easier to pick and shell a quart of them than the common limas, and they are certainly fully equal for table use. We planted quite a large patch of them last season, and we propose this season to plant a larger patch. Price 5 cts. a package; 15 cts. per half-pint; 50 cts. per quart; \$2.75 per peck, or \$10.00 per bushel.

THE CARPENTER'S STEEL SQUARE, AND ITS USES.

After long months of waiting and putting off our customers having orders in for the above book, we finally gave up all hopes of getting them again from the publisher, and accordingly sent back the money we had received, and crossed them out of our book-list. No sooner had this been done than we received word from the publisher that the books were out at last. We sent him an order by first mail, and now have 200 in stock, ready to send by return mail for 17 cts. each, postpaid, or 15 with other goods by express or freight.

JAPANESE BUCKWHEAT.

We notice in most of the seed catalogues so far, that seedsmen are asking \$3.00 per bushel, retail, for new Japanese buckwheat. No doubt this extra price is to help pay for fancy lithograph covers and chromo pictures that come with the catalogues; but please remember that *our* price is only \$2.00 per bushel; \$1.25 per $\frac{1}{2}$ bushel; $\frac{1}{5}$ cts. per peck. In lots of five bushels or more, \$1.75 per bushel. We have a very large stock of very choice seed. We have made arrangements with a party in Wisconsin, whereby we can fill orders from that point, of two bushels or more, to customers in the West, to save freight.

PRICE LIST OF DOVETAILED HIVES.

We append here a list of prices on the Dovetailed hive, illustrated and described elsewhere in this issue. Please notice that we give prices in different quantities per hive, under the quantity named at the top of the column.

DOVETAILED HIVES PUT UP AND IN THE FLAT.					
Description.	Price each.	In lots of—			
		1	5	10	20 50
No. 1. Eight-frame Dovetailed hive, shown to the right, over, with one bottom, body, one super, slatted honey-board, 8 all-wood frames and cover, 1½ story, for comb honey, complete, put up and painted.		1 50	1 45	1 40	1 35
No. 1. Eight-fr. Dovetailed hive in flat, with sections, starters, and tin sep's.		1 20	1 00	90	85 80
No. 1. Eight-fr. Dovetailed hive, in flat, with frames and section-holders, but no sections, starters, nor separators		90	75	70	65 60
No. 2. Eight-frame Dovetailed hive, shown to the left, over, is furnished just like No. 1, with one more super added, making a two-story hive complete, put up painted.		2 00	1 95	1 90	1 85
No. 2. Eight-fr. Dovetailed hive in flat, with sect's, starters, and separa's.		1 50	1 30	1 25	1 20 1 15
No. 2. Eight-frame, Dovetailed, in flat, with frames and section-holders, but no starters, separators, nor sections		1 10	90	85	80 75
No. 3. Same as No. 1, except that it has T tins in the supers, instead of section-holders. Same price.					
No. 4. Same as No. 2, with T tins instead of section-holders. Same price.					
We will make the Dovetailed hive 10-frame instead of 8-frame, in any of above numbers, as follows:					
Nailed and painted, complete, 20 cts. each extra.					
In flat, complete, 15 cts. each extra.					
In flat, without sections, starters, or separators, 10 cts. each extra.					

KIND WORDS FROM OUR CUSTOMERS.

GLEANINGS is so valuable and interesting I should not want to do without it.
New Philadelphia, O. DR. G. L. TINKER.

Really, Bro. Root, and no "taffy," GLEANINGS does grow better and better. Thank you for the biographies. They are good.
N. Searsmont, Me., Jan. 9, 1889. H. E. MILLER.

The type-writer came all right. We are very much pleased with it. It is very nice, and a better machine than we supposed it to be.
Wells, Minn., Dec. 31, 1888. J. P. WEST.

We were really delighted with the account of the travels in California. Your way of describing it, and mentioning the little things, makes a person seem to be traveling with you. We think Ernest did well upon GLEANINGS while you were gone—not only well, but splendid. He gave us an excellent GLEANINGS, especially the last one.
Roseville, Ill., Dec. 15, 1888. MRS. L. C. AXTELL.

KIND WORDS FROM SWEDEN.

After describing our A B C book, our good friend Hj. Stahlhammer, editor of the *Svensk Bitidning* (*Swedish Bee-Journal*), deposes as follows in regard to the author of the book:

Mr. Root's name alone is a guarantee for the worth of this book—a man of whom it may be said, "In him falsehood finds no place," and who in faith and business is a Christian in the best sense of the word. We can, therefore, recommend this book in the highest terms, as it is fully up to the times.

[If the above is "too good," we hope it will be excused by the fact that our education in the Swedish language was somewhat neglected when we went to school, and hence a "new version" might modify the meaning somewhat. But we strongly suspect that the "sum and substance" is about all right.]

A B C OF BEE CULTURE.

"What's that?" remarked the editor as a package was handed him. As no one replied, he thought it might be well to investigate. Was it a bomb? Never! It was a copy of the "A B C of Bee Culture," that pioneer book on the art of progressive bee-keeping, which gives its readers the bee-fever so badly that sometimes they never get over it—you see it's worse than a bomb (?) for the bee-keeper. The book has now reached its 37th thousand; been recently revised; many new engravings added, and, to make it what friend Root used to call a "whooper," the biographies of 21 "noted bee-keepers" add much to its value. The great beauty of this work, it seems to us, lies in the simplicity and clearness with which all the details and manipulations are given; making it pre-eminently a book for the beginner. It is published by A. I. Root, Medina, O. Price \$1.25.—*Bee-Hive, Jan. 1.*

WHAT A. E. MANUM THINKS OF GLEANINGS.

I can not let the year 1888 pass away without returning to you the warmest thanks of one who is a steady reader of *GLEANINGS*, for the good work you have accomplished in the past few years. It has been an era of great success to you, and, as I firmly believe, a great benefit to the many bee-keepers of this country. Although the year 1888 has been somewhat disastrous to the bee-keepers of America, your good and timely counsel has given courage and hope that the coming year will bring prosperity and gladness to your many readers. You are entitled to the thanks of the great body of bee-keepers, and the increase of your circulation shows that many of them are not unmindful of their obligations. You have given us a bright, clean, able, educational magazine at one dollar a year, which shows hard work and good business management, and I am pleased to notice the success which is so justly your due. A. E. MANUM.

Bristol, Vt., Dec. 27, 1888.

WHAT TO DO, AND HOW TO BE HAPPY, ETC.;
WHAT A READER OF THE BOOK SAYS OF IT.

On receiving your book, "What to Do," I thought I would write just a formal note, acknowledging the receipt of the same. I began to read the book, became interested, and put off writing, until now I feel under obligations to give you my sincere thanks, for the pleasure and instruction contained therein. To simply say, "I like the work," seems cold and expressionless; therefore I will say it gave me real pleasure to read it, and I believe it will be greatly to my benefit to obey its instructions.

A great many books are written, giving instructions in garden and farm work, which are so filled with technical terms it is hard to find out what they mean. The language in "What to Do" is very easy to understand, and its author seems each time to put just the right word in just the right place. In some other works of this kind (if their author's plans were carried out) it would require a very heavy outlay of money, which the poor farmer or gardener could in no wise afford for the purpose. The plans in this work do not call for any very great outlay of money, but such outlay as most men can afford who follow the business of either farming or gardening. I speak of farming and gardening both, because the reading of your book would benefit both.

I own a small farm; have lived nearly all my life

on a farm, and am deeply in love with farming as an occupation at once "the most ennobling and healthful" of any. A good garden is a great advantage to the farmer who gives a share of his time to its culture, but by many farmers it is often neglected. Of course, any book which helps in gardening would also help in farming.

There is another feature shown in your work, which makes me wish I were personally acquainted with its author; and that is the trustful leaving of all things in the hands of "Him in whom we live and move and have our being." Each chapter is introduced with a text—an appropriate beginning surely—and love to God and your fellow-man seems no small share of the whole work. I have derived great pleasure in the reading of the work, and great satisfaction in thinking its author was a child of God, and that, while he was instructing some how to sow seeds and cultivate them, he was himself sowing seeds of immortality which might spring up and bear fruit which never would decay. Now I trust I have not tired you, for less would not satisfy me. I hope we may meet at some future time, and may that hope become a certainty. We are both striving for a crown of glory, and may we both be so blest as to win and wear it.

JAMES A. FIELD.

Farmer, Defiance Co., O., Jan. 26, 1889.

WHAT TO DO,

—AND—

How to Be Happy While Doing It.

The above book, by A. I. Root, is a compilation of papers published in *GLEANINGS* in 1886, '7, and 8. It is intended to solve the problem of finding occupation for those scattered over our land, out of employment. The suggestions are principally about finding employment around your own homes. The book is mainly upon market-gardening, fruit culture, poultry-raising, etc. I think the book will be well worth the price, not only to those out of employment, but to any one who loves home and rural industries. Price in paper covers, 50 cts.; cloth, 75 cts. If wanted by mail, add 8 and 10c respectively.

A. I. ROOT, Medina, Ohio.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock, and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

FOR SALE.—A few black and hybrid queens, 35 and 50 cents. YOUNG G. LEE, Charlotte Harbor, Fla.

Wants or Exchange Department.

Notices will be inserted under this head at one-half our usual rates. All ads intended for this department must not exceed 5 lines, and you must say you want your ad in this department, or we will not be responsible for any error. You can have the notice as many lines as you please; but all over five lines will cost you according to our regular rates. This department is intended only for bona-fide exchanges. Exchanges for cash or for price lists, or notices offering articles for sale can not be inserted under this head. For such our regular rates of 20 cts. a line will be charged, and they will be put with the regular advertisements.

WANTED.—Man and wife to keep house for a farmer (single man). Good house of seven rooms. Two miles from postoffice. No better place in Ohio for bee-keeping or market-gardening. Chance for an enterprising man to handle several colonies, as farm is $1\frac{1}{2}$ miles long by $\frac{1}{2}$ mile wide. Four manufacturing towns from 2 to 8 miles from farm, with populations of 503, 2500, 10,000, 25,000. No farm hands to board. 6d R. L. KING, Vanlue, O.

WANTED.—To exchange 250 colonies of bees, for horses, mules, wagons, buggies, and 4 h. p. engine, or any thing useful on a plantation. 21tdb ANTHONY OPP, Helena, Phillips Co., Ark.

For Sale Cheap.

The apiary (140 stands of bees, hives, etc.), belonging to the estate of Dr. G. W. Young, deceased. A rare opportunity. Address 5-6-7d ALBERT G. YOUNG, Adm'r, Lexington, Mo.

THIS unique little engraving represents Cupid "clothed and in his right mind." It also shows that, when busy with the pretty flowers, he has no use for his bow and arrows. The fiery darts lie unused at his feet. His action in this

respect reminds us of one trait in the character of a bee: when intent upon the blossoms she has no inclination to use her "fiery dart." There is, however, quite a difference in bees in this respect. Some are far more inclined than others to thrust in the "barbed arrows." In the character of bees there are still other peculiarities. Some are more industrious than others; some cling more tightly to the combs; some cap the honey more white; some work more readily in the supers, etc. There is not space here to enumerate all the characteristics of each variety of bees; but in the

BEE-KEEPERS' REVIEW

for March much space is given to the discussion of: "Which are the best bees?" The same bee may not be the best for every purpose and all localities. If you are in doubt as to which is the best bee for you, read this number. It will be sent free, and with it will be sent the May and June numbers of 1888.

Price of the REVIEW, 50 cts. a year. Back numbers furnished.

The Production of Comb Honey is a neat little book of 45 pages; price 25 cts. This book and the REVIEW one year for 65 cts. For \$1.00 the REVIEW will be sent two years, and the book "thrown in." Stamps taken, either U. S. or Canadian. 613 Wood St. W. Z. HUTCHINSON, 6d Flint, Mich.

HONEY COLUMN.

CITY MARKETS.

KANSAS CITY.—Honey.—Fair demand for comb honey. Extracted, scarce and in good demand at 8 cents for both white and amber.

Mar. 9. CLEMONS, CLOON & Co.,
Kansas City, Mo.

ST. LOUIS.—Honey.—Actually there is no demand, and, with the exception of occasional inquiries, the market is quite dead.

Mar. 9. D. G. TUTT GRO. Co.,
St. Louis, Mo.

DETROIT.—Honey.—Sales continue to be slow; supply about equal to the demand. The quality seems rather poorer than usual. Quotations same as last. *Beeswax.*—There is a little more call for this, but no change in prices.

Mar. 9. M. H. HUNT,
Bell Branch, Mich.

BOSTON.—Honey.—Our market is very strong and active for white honey. We quote: Best 1-lb. comb, 18¢@20; 2-lb., 16¢@18. Extracted, 8¢@9.

Beeswax, 24. Stock on hand very light.

Mar. 9. BLAKE & RIPLEY,
Boston, Mass.

CHICAGO.—Honey.—Honey sells in a small way at 16¢@17 for the best white comb, in pound sections; all other grades of comb are dull. Extracted is steady at 7¢@8; off color and dark, 6¢@7. *Beeswax*, 22.

Mar. 8. R. A. BUENNETT,
161 So. Water St., Chicago, Ill.

CINCINNATI.—Honey.—There is no improvement in the market excepting in the demand for dark or extracted honey, which is scarce. We quote extracted honey at 5¢@8 on arrival. Comb honey at 12¢@15 in the jobbing way. *Beeswax.*—Demand is good at 20¢@22 on arrival for good to choice yellow.

Mar. 11. CHAS. F. MUTH & SON,
Cincinnati, Ohio.

FOR SALE.—Ten 60-lb. cans of first-class extracted honey, at 8c per lb.; has just been liquefied, and will pour readily from cans. Sample for 2-cent stamp.

R. I. BARBER, E. Washington St.,
Bloomington, McLean Co., Ill.

I still have a few 60-lb. cans of choice light honey that I will sell at \$5.00 per can (60 lbs. net), sample free.

OLIVER FOSTER, Mt. Vernon, Linn Co., Iowa.

FOR SALE.—1500 lbs. of clover and heart's-ease honey, mixed; by the barrel, 7c; in 60-lb. square cans, 7½c, F. O. B. cars at Dixon. Samples free by mail.

EZRA BAER, Dixon, Ill.

OUT-APIARIES. NO. III. — CONTINUED.

DISTANCE APART.

SUPPOSE the home apiary is located at *a*. With *a* as a center, draw a circle *bc*, the points *b* and *c* being distant three miles from *a*. The first series of apiaries will be located somewhere in the curved line *bc*; and if just three miles apart, there will be six of them, *b*, *d*, *e*, *c*, *f*, and *g*. We may represent the range of the home

apiary by the circle *hi*, and the ranges of the other apiaries by circles of the same size. These circles representing the range of each apiary are arbitrarily assumed, and may be too large or too small, the supposition being that the ranges overlap a little at their outer edges, where the interference will not amount to much. This makes, including the home apiary, a series of seven apiaries. If it be desired

to increase the number, or if the pasturage be such that it is desirable to omit some of these and plant others to one side, we can find the location for one at *k* by finding a point three miles distant from each of the points *b* and *d*. *l* is equidistant from *b* and *g*, and *m* equidistant from *k* and *b*, and, for that matter, from *l*. If we complete two circles at these distances, we shall have altogether 19 apiaries, the furthest of which shall be only six miles from home. I think I'll not carry the thing any further than 19. Let Capt. Hetherington make his own plans. All this looks very easy and very regular on paper. In actual practice it will be quite different.

If you have a township map, cut an equilateral triangle out of card-board, each side of which shall measure three miles on your map, and you can easily lay off your ground, for *a*, *b*, and *d* make an equilateral triangle, so do *a*, *d*, and *e*, and so on.

Marengo, Ill.

C. C. MILLER.

Well, old friend, I think you would get pretty much all the honey, if you covered a field as illustrated above, any way. During an excessive yield there might not be bees enough to consume it all; but I think that, with an apiary every three miles, as you have planned it, there would not be very much wasted any season. During poor seasons I am afraid the two apiaries in the middle, *a* and *b*, might have a pretty tough time of it, especially if all the surrounding apiaries turn in and learn the trade of robbing. By the way, do robber-bees ever go three miles? When I was thinking about getting a locality for queen-rearing, where no robbers would interfere, I thought that, if I could go about a mile and a half from any other bees, it would do very well. In our locality I am pretty certain that bees are not

often found three miles from home at any season of the year. But to cover the ground as you have planned it, I believe I should want as much space between them as three miles; therefore, all things considered, I should say you have got it about right.

RAMBLE NO. 12.

SOURING HONEY, ETC.

Flow, softly flow, by lawn and lea;
A rivulet, then a river,
And here by thee will hum the bee
For ever and for ever.

NIG'S feet having been put in proper order, they patted down in staccato time as we bled away again over hill and dale, by quiet forest shades and over babbling brooks, until our course was arrested by what is popularly known as Hall's Mills—a gristmill, sawmill, cider-mill, a potato-hook mill, and, besides all these, a honey-mill, or, in other words, Mr. Hall, not getting filthy lucre fast enough, he thought he saw a great bonanza in the production of honey, and enthusiastically stocked up, with bees, bee-journals, etc. A severe winter loss caused a perceptible decline in enthusiasm. Then a few seasons of short yields caused the abandonment of bee-journals, and a general neglect of both bees and honey; and it is evident that Hall's bees will not hum by this rivulet, "for ever and for ever."

The Rambler found four barrels of honey, rolled out at the rear of the house, under the eaves, with the honey in all more or less sour. This, when extracted, was evidently a good quality of clover honey; but being left in a damp cellar, with bungs out, it had absorbed so much moisture as to make it a damaged article, and it was finally rolled out to make room for cider. If this honey had been stored in a dry room, the quality would not have been injured. The opinion people had of it was fully expressed by Mrs. Hall asking the Rambler if his customers for extracted honey ever wanted any the second time. When told that many customers laid in a supply every fall for winter use, year after year, many preferring it to comb honey, she was incredulous, and said their customers never came for extracted honey the second time; and it was even hard to sell comb honey to those who had used their extracted honey.

As the Rambler went on his way again, the thought uppermost in his mind was the great fact that many people are induced to keep bees who are not and never can be fitted for the business; and the production and sale of honey in many localities is injured more by incompetent local producers than by any other cause. The Rambler does not encourage everybody to keep bees.

LUTE VIRGIL.

The sun was just descending behind the western hills, the lovely autumnal tints blending to charm the eye, while the musical notes of the fall cricket rose and fell in rich cadence from orchard and meadow, and the Rambler would fain lay himself down upon some mossy bank and sweetly dream of the hum of bees and a flowery land. The real hard struggles of life were, however, before me; the farmers were coming in from the toils of the day, with sweat-bedewed faces, tattered clothes, and calloused hands that silently spoke of the hard struggle with nature. A few of the "cattle from a

thousand hills" were being herded for the night, and all signs admonished the Rambler to hasten to a haven for the night, under the roof of Mr. Lute Virgil, a noted bee-keeper of Whitehall. Bro. V. lives upon one of the world's byways. We go down through a dark ravine. The stalwart trees on either side, like huge sentinels, seem to guard the rocky pass. When safely down we come out on a broad alluvial bottom, and this is called an interval on Wood Creek. A sharp turn to the right soon brings us to a cosy cottage, under a perpendicular rocky cliff of over sixty feet in height. As it is east of the house, old Sol puts in a late appearance at the Virgil homestead. I found Bro. V. attending to the chores, after the completion of which we adjourned to the house, where I found Mrs. V. and two bright little girls to enliven the home and to make it worth loving and living for. Nearly all of the bee-journals are found upon his table, and we found his preferences strong in particular directions. A worthy man named Doolittle scemed, according to Bro. V.'s dictionary, to be the only writer of much consequence in the apicultural ranks. To sum up the main points of our conversation during the evening, I find it ran about as follows:

"Well, Bro. Virgil, I did not see your hives as I entered your grounds this evening; you must paint them a dark color."

RAMBLER'S DREAM—FOLLOWING IN THE TRACKS OF DOOLITTLE.

"Oh, ho! friend R., I follow nature; take Doolittle's advice, and don't paint them at all. Bees winter better in unpainted hives. I don't believe in any fancy fixings or poetry about hives and yards, etc. I run my bees at the least possible expense. I am after the hard dollars."

"Then I suppose you use the Doolittle hive."

"Oh, no! I use the Langstroth hive; but if I had known as much about Doolittle's plans as I do now, I would have adopted his hive. His big yields of honey every year show that the hive enables him to get there every time."

"Then I suppose you don't think much of the new-fangled Heddon hive."

"Well, no! You see, Doolittle don't say much about it."

"Well, Bro. V., do you practice artificial swarming?"

"No, sir. You don't catch me so far from nature's plan as that. Doolittle and I agree on swarming, exactly."

"I see you have Alley's Handy-book; how do you

succeed in raising queens according to his particular method?"

"Why, now, friend R., you make me tired. Just think of the fixin's and palaverings with shaving combs, hot beeswax, matches, and tin feeders! Why, Doolittle's natural plan just fits into my hat, and we get there with big queens and tons of honey every time."

"Do you raise comb or extracted honey?"

"I raise gilt-edged comb honey. I don't expect to equal Doolittle just yet, but I mean to get there."

Finding I could not get Bro. V.'s mind from the great bee-man, we talked crops and farming generally, but Doolittle's name would get mixed in with corn, potatoes, and the care of stock.

At the table, when he passed the articles to me I expected him to say, "Will you take some more Doolittle?" like the girl passing potatoes to a man with an enormous nose. The nose fully absorbed her mind, and, said she, "Sir, will you have some more nose?"

Dreams troubled the Rambler again, and it seemed as though we were all following Doolittle; and in this direction I am free to confess are often found the steps of the

RAMBLER.

THAT RACE BETWEEN BEES AND PIGEONS.

THE MATTER EXPLAINED.

MR. EDITOR:—On page 935, for 1888, you copy an item from the *Bee-Keepers' Record* about a flying-match between pigeons and bees. You reserve prudently your opinion on the story, for want of facts. I am able to give you information. The German *Bienenzeitung* first reported the match, whence it has been translated in so bungling a manner that it became indeed a very ridiculous yarn. A correct translation will change it into a serious and interesting experiment. It reads as follows:

From Hamm it is reported that one Mr. Ch. R., a fancier of carrier-pigeons, and a bee-keeper, proposed the following match: The distance was to be not quite one hour (about $2\frac{1}{2}$ miles), namely, from Rhynern to Hamm. The day selected was fine, when bees would come home sooner than carrier-pigeons. The bet was taken . . . and bravely won by the bee-man. Twelve carrier-pigeons and twelve bees, sprinkled with flour, 4 of which were drones, were taken to Rhynern, and there simultaneously set free. One white drone arrived 4 seconds in advance of the first pigeon. The second pigeon arrived simultaneously with the other three drones, and together with the rest of the pigeons arrived also the workers. The bee-keeper had won the match."

You will, by comparing the above with the rendering in the *Record*, easily understand that the translation has been made by a man equally igno-

rant of the German language and of apiculture (which he confounded with agriculture). He omitted to say that the bees were sprinkled with flour, because he did not know what every bee-keeper knows, that it was essential, as otherwise the bees could not be identified. Not quite one hour is about $2\frac{1}{2}$ miles (English), not 5 miles. The German term *langten an*, which means *arrived*, is, by the ignorant fellow, translated "preceded by a length." Any schoolboy would not have made such nonsense. The fact that pigeons are beaten by bees is not new.

Sigel, Ill., Feb. 15, 1889.

DR. WM. LEERS.

SOMETHING NEW FOR HONEY AND MAPLE SYRUP.

RECENT IMPROVEMENTS IN THE WAY OF CANS FOR MAPLE-SYRUP MAKERS AND SHIPPERS.

MOST maple-sugar makers have experienced the awkwardness of trying to box up the ordinary round cans, whenever they are so lucky as to have an order for syrup from a distance. Well, this season, for the first time, we have got a gallon can that fits into an ordinary square box as nicely as a duck's foot fits in the mud. If you don't believe it, look at the "picter."

Now, if you should be so lucky as to have an order for ten or a dozen cans, you can just set them all in one box made purposely for shipping syrup, as in cut below.

Of course, all I have said in regard to the adaptability of these cans for maple syrup will apply with equal force to putting up and shipping honey. In fact, we keep them in stock all the year round.

A BOX HOLDING TEN ONE-GALLON CANS FOR MAPLE SYRUP OR HONEY.

Price of the one-gallon cans, not boxed, \$12.00 per 100; same boxed, 10 in a box, \$14.00 per 100; single box of 10 cans, \$1.60. Single can, without any boxing, 15 cts.

BEE-FOOD IN WINTER.

THE BEST OF THEORIES MUST VAMOOSE BEFORE
CONTRA FACTS.

WHEN I answered Question 97, in GLEANINGS, I did so from my experience in bee culture for the past twenty years. I, also, have some theories and a slight knowledge of chemistry as connected with apiculture; but the latter are not great enough to cause me to rely upon them when my practice with large apiaries teaches me differently; but it happens that my theories regarding transpiration, ventilation, and the component parts of winter food, precisely agree with my experience, nearly all of which ground you have been over in your experience, as indicated in your foot-notes to Bro. Corneil's article on page 172. I love theory; still I am aware that there is both true and false theory. I strongly incline toward those minds which take to theorizing, and who study and love science; and I value Mr. Corneil's scientific articles, but I know positively that, in the depths of his research, his lantern has gone out, and he thinks he feels something that doesn't exist. I know that bees can and *do* and *did* continue to digest syrup without the least particle of pollen in the hive. Practically I know nothing of the component parts of sugar, only so far as I believe the statements of chemists, and especially of our friend Professor Cook. I believe that I never said that my bees starved on sugar syrup. I said that they froze to death during the longest and severest cold spell I ever witnessed. Bees kept upon natural stores did the same; but I did bring through 73 colonies upon sugar syrup, and in perfect condition. There were very few dead bees, and not the least sign of the old malady we have called bee-diarrhea or bee-dysentery, so that, when they had their first flight on the 17th of April, warm and pleasant, and the outside bees were gathering pollen, not a bee of the 73 colonies voided any thing, not even water. Their bodies were just as slim as when placed in winter quarters. I call that perfect wintering, as they were confined in the cellar 151 days with absolutely no food in the hive except strictly pure granulated-sugar syrup acidized with tartaric acid. I honor Mr. Corneil for his careful research, but I know that he will be compelled to search again.

DOVETAILED HIVES.

When I see something in GLEANINGS relative to mechanical construction of hives I am at once interested; for, more than all other branches of apiculture, have I made this a study, and with it have I experimented. While William Stolley, of Grand Island, Neb., was my foreman I devised this same honey-board with the full bee-space on either side, and he assisted me in making it; or perhaps I am mistaken, and it was W. H. Shirley, of Mill Grove, Allegan County, Mich., who helped me make some of them at our mill, one or two samples of which still hang in my shop. The brood-frames to use in that case were to come flush with the top of the hive, of course, the bee-space being in the honey-board. It has never gone into general use with us, and I think it never would, even were we to continue using the old Langstroth hive and suspended frame. Now, the dovetailing arrangement, you may well imagine, was talked over much by us, believing as we did that it would be the best way with which to make our shallow cases, which with the

new hive you know I use in the brood-chambers the same as in the surplus cases, and we came near getting machinery to make them in that way, but did not do so. I believe it is a move in the right direction; and with your shop-room, power, fine machinery, and large trade, I believe it is practical and best to adopt dovetailing for hives, supers, etc.

No, I do not favor discarding the bee-space at the top of the L. hive, nor do I believe the section-holders illustrated on page 189 will come into general use. I will not occupy your valuable space at present by telling why; but you make one of my points when you say that honey is cheap, and we must have simple and cheap implements. Where no separators are to be used, I believe nothing is better than my old-style case, but I would advise making it with dovetailed corners, and grooves in the sides for divisions. Certainly you are privileged to not only use but manufacture for sale my break-joint and bee-space honey-board, when used either with or without queen-excluding metal, or, for that matter, any of the parts connected with my modification of the Langstroth hive; and, more than that, I wish to thank you for your manly method of giving credit to whom you believe it belongs. Of course, you have not forgotten how almost alone I pleaded for the honey-board; but a writer in the *Canadian Honey-Producer* seems to have forgotten that almost alone I also pleaded for the tiering-up system long before he ever uttered a word about it, as the records show, and no doubt before he had any conception of its usefulness. It is tedious, to say the least, to plead for certain manufactures and systems of manipulations for years, opposed and almost alone, and, after succeeding in popularizing it, to have some one come up, like a Jack out of a box, and lay claim to the results of your labors; but we must learn to bear and forbear.

Dowagiac, Mich., Mar. 5, 1889. JAMES HEDDON.

You will see, by referring to department of "Recent Developments," elsewhere, that we have decided to put the bee-space *above* the frames instead of below, and, of course, use a one-bee-space honey-board.

ANOTHER HEXAGONAL APIARY.

SESPE APIARY, FILLMORE, CAL.

I DID not think to tell you about my hexagonal apiary when you were here, so I send you a plan of it now. The little round spots are stones about as large as a man's head, 8 in a pile. They answer a double purpose. They are put on the hives in the winter to keep the covers from blowing off, and when a hive has a virgin queen one of them is put near the entrance to mark the hive until she is laying. The hives all face those stone piles, and the honey-carts are run up through the other hexagons between the backs of the hives. Those other marks between the stones are nucleus hives. The advantages of this arrangement of the hives are, that the bees do not work to the out ends of the rows, and become weak in the center as they do when the rows are straight, and queens are seldom lost on their wedding-trip. The only disadvantage I know of is the difficulty in getting the honey-cart to stand close and at right angles to the inner hives when taking out honey. The land slopes south to the honey-house; hives face east and west,

and brood is always placed near the south side of hives in the spring.

J. F. MCINTYRE.

Fillmore, Cal., Jan. 21, 1889.

Friend M., we are very greatly obliged to you. I was very much interested, in fact, in your hexagonal apiary; but those great mountains before and behind your pretty little ranch kept me staring so much of the time with open mouth that I am afraid I did not look at the apiary as much as I might have done otherwise. Perhaps not all the readers may be as fortunate as you are in having access to stones of any particular size you may happen to need. I want to explain to the friends, that right in front of his house a big block of granite about the size of a meeting-house stands as tranquilly and unconcerned as if it had a perfect right there; but friend M. told me,

cartload of honey goes down through those open lanes without much labor. Between the honey-house and the road is a great iron tank. These iron tanks are to be seen near every honey-house in California. An iron pipe runs from the extractor into the tank; then a gate at the bottom of the tank lets the honey into the square cans, standing on a platform just right to load into a wagon. There is no need of building any roof over the tank, for it never rains in California during the honey-flow. You will find a photograph of some of the mountains back of Sespe Apiary, in our A B C book. Right back of the apiary, on the western slope, is an irrigating canal that pleased me greatly. It is a sort of wooden flume; and the sight of the pure babbling brook that glides down over the sandy and gravelly bottom, as if it

were in a big hurry to get somewhere, was to me a fascination. These streams of watermean business — market-gardening, fruit-raising, etc. The picture of R. Wilkin's apiary, in the A B C book, does not begin to do justice to the spot. The trees seen scattered about are orange and fig trees, and the oranges and figs are good too.

Do you want to know what our young friend McIntyre is doing with R. Wilkin's apiary? Why, he married friend Wilkin's youngest daughter—that is how it comes about. Oh, yes! I want to tell you one thing more about young McIntyre: He is a young Canadian, like "our John;" and I tell you, friends, when you find better boys to work than these young "Canucks" you will have to fly around lively. When friend Wilkin was putting up his shipload of honey to take to Europe there was a great demand for tinner, to solder up cans. The best tinner in San Buenaventura succeeded in soldering only about 1100 cans a day; but friend McIntyre, after a couple of weeks' practice, solder-

ed up 1400.

This is the same apiary that E. Gallup had charge of some years ago. Friend G. is now located in Santa Ana, near Los Angeles, but he was not keeping bees when I called upon him.

DO LIZARDS EAT BEES?

PROF. COOK TELLS US SOMETHING ABOUT THE LIZARD FAMILY IN GENERAL.

MR. J. M. WOODHOUSE, Durango, Dubuque Co., Iowa, writes: "There is a small quadruped, about six inches long, with striped body and blue tail. It lurks about my hives, burrowing last summer under an empty hive in the bee-yard. What is it? Does it eat bees or honey, and is it poisonous?"

This is doubtless *Scincus fuscatus*, Holbr.—the blue-tailed striped lizard. This lizard is about eight inches long when full grown. Its head is bluish black, with six light-yellow lines, and its

PLAN OF SESPE APIARY, BELONGING TO J. F. MCINTYRE, FILLMORE, CAL.

when I looked at it in a questioning way, that it came down the canyon one night in a flood, and stopped right there. In my innocence I spoke about following the path up to the summit of a mountain right across the stream, while waiting for the buggy. They said I would not have time, and asked me if I noticed some animals away up on the summit of the mountain. I told him I saw some little black pigs, if that was what he meant; but after I looked carefully, the little black pigs seemed to have horns on their heads. When told they were cows, the mountain seemed to spring up a quarter of a mile all at once, and I concluded I would not go up where those little cows were, especially as we hadn't more than an hour to spare.

Do you want to know something more about the apiary? Well, Sespe Apiary, as they call it, is one of the prettiest I ever saw. The honey-house is at the foot of the incline, just below the bee-hives, so that a

body the same color, with five straw-colored lines. The tail is deep blue. The throat and abdomen are white. It belongs to the "skink" family of lizards.

Lizards—from their quick lively movements often called swifts—do live on insects. I have never known or heard of their eating bees; but the toads do, and why may not the lizards as well, as they too are insectivorous? I do not think, however, that they will do any very considerable harm. None of the lizards are in the least poisonous, or harmful to handle. Even the horned toads of Colorado, Kansas, and Texas—these are also lizards and not toads at all—which, from their horns, or spines, look quite formidable, are quite safe to handle.

Very likely the lizard may visit the cellar. They have been found in cellars often.

Mr. Woodhouse also asks if there is any positive evidence that bees mean to kill a queen when they ball her. I think there is the best of evidence. I have seen several queens balled, and soon afterward found them dead in front of the hive. That the bees sometimes relent, and do not execute their intentions, is equally obvious, for I have known more than one case where a balled queen left alone was permitted to escape, and did excellent work as the mother of the hive for months afterward. I think the bees intend execution when they surround a queen. Why they change their minds in some cases, I can not say.

Agricultural College, Mich.

A. J. COOK.

I saw a great many beautiful lizards in California. They would glide along the rocks on which we were sitting, and peek at us curiously out of the cracks and crevices. I think it quite likely they might learn to eat bees to some extent.—In regard to bees killing a queen when they ball her, the most of us have had ample proof, by sad experience, that they do usually kill them unless driven away by smoke, or made to let them alone by recaging or something of the sort.

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

SETTING OUT TREES: HOW TO DO IT BY MEANS OF HEXAGONS.

ON page 980 of GLEANINGS, Dec. 15, you ask if any of your readers can tell you how the orange groves are planted so as to line at so many different angles. Yes, I think I can.

The properties of the hexagon will explain it. You go to the honey-bee again for wisdom. Take a

hexagonal piece of card and lay it on a piece of card-board, at the upper left-hand corner, to correspond with the dots of pencil. Move it to the right one-half of its diameter, and mark its angles and center. Keep on at this across the card, then place the hexagon just below the first diagrams made, and go across the same way. Continue this process *ad libitum*; then you can draw lines to represent the rows, as I have done, showing six angles at which they will row, or "line."

More trees can be set at a given distance apart on the same land, this way than in any other I know of. I have been in the fruit-business quite extensively, and have given the subject much thought. The properties of the hexagon are very useful in the solution of problems in geometry and trigonometry, as no doubt Ernest can testify. If any one gives a plan that is ahead of this, let us have it in GLEANINGS. I hope you will keep on traveling, and writing notes. I think your Notes and "Our Homes" the most valuable part of the book.

Brookston, Tex.

J. G. FITZGERALD.

We are all very well aware that the figure you give is the way trees should be set; but I can imagine that the greater part of us will have great difficulty in setting them as accurately as you have drawn your lines. Perhaps by the aid of the appliances given in our former numbers we may be able to do it. The orange-groves—in fact, orchards of almost all kinds in California—are set out in just this way. Each tree is the center of six other trees, all at equal distances from it and from each other. Some may say that it is too much fuss and bother; but, my friends, it pays to spend some time in fuss and bother when you realize that an orchard may stand not only during *your* life, but for the benefit of your children also. In cultivating, our California friends just pull their harrows through between the trees, in three different directions; and after they get done, the ground looked "handsome," I tell you.

THE IGNOTUM TOMATO. REPORT FROM PROF. BAILEY.

At least two or three thousand of our readers will be interested in the following, which we take from the *American Garden* of March 1:

This variety has been mentioned of late in several journals, and it therefore seems proper to say something concerning its origin and merits. During three years the Michigan Agricultural College has undertaken extensive tests with tomatoes, and for two years all varieties that could be secured from all sources were grown. In the spring of 1887 a complete set of German varieties was obtained from Robert Neumann, of Erfurt. Among them was the Eiförmige Dauer. This proved to be a small and angular variety of no promise; but one plant bore fruits of remarkable beauty, solidity, size, and uniformity. Among about 170 sorts shown that year at the State fair at Jackson this tomato stood up far the best of any. I supposed this plant to be an accidental mixture in the seed of Eiförmige Dauer; but being unable to determine it I called it Ignotum, or "unknown." In the spring of 1888 a few seeds were sent to several friends for testing, and some 500 plants were set in our own garden. Everywhere the variety appears to have exceeded expectations. I left the Michigan College in August, and therefore did not see the full fruitage of the plants; but my former foreman, Charles S. Crandall, a thoroughly competent observer, informs me that it maintained its excellence, but that a few plants reverted to the Eiförmige Dauer, a fact which indicates that the Ignotum is a sport

FITZGERALD'S METHOD OF MARKING THE SITE OF TREES.

from that variety, instead of having been a simple admixture in the seeds. Others, including E. S. Goff, at the New York Experiment Station, had similar results. It is to be hoped, therefore, that seedsmen will not be tempted to secure the variety until two or three years further selection give it a thoroughly stable character.

My successor, Professor Taft, makes the following observation concerning my last plantation of Ignotum: "From our own experience, and the reports of others who have tried it, I am inclined to think that it deserves a front rank among the tomatoes. With us, as compared with the Mikado, it is larger, smoother, more solid, less subject to rot, more productive, and is more desirable, both as an early and as a late variety. We had several hundred plants growing on a dry sandy knoll; and although it was a dry year with us, the plants gave a very heavy crop, and continued ripening until the frost destroyed the plants about the first of October."

Mr. A. I. Root, to whom a few seeds were sent, makes the following statement in his GLEANINGS IN BEE CULTURE: "The first ripe tomatoes I picked in the open ground were from a dozen vines of the Ignotum. It is remarkably free from rot, ripens all over alike, and each vine bears a great quantity of tomatoes. I do not know that we have any tomato in any respect superior, except the Mikado, and the Mikado excels only in size. Perhaps this is owing, however, to the fact that our Mikados of the past season were all from the seed taken from a tomato that weighed a pound and a half. The result of this selection of the seed gave us extra large Mikados, but it did not mend the awkward shape of a great part of the tomatoes very much. To sum it all up, then, the Ignotum tomato, in my estimation, is ahead of any thing heretofore introduced."

Four tomatoes have given us great satisfaction in outdoor culture, in the order named: Ignotum, Puritan (from Rawson), Potato Leaf (from Livingston), and Mikado. Mikado is too irregular, and is not uniform in size; but its great size and productiveness are merits which can not be overlooked.

Ithaca, N. Y., Feb. 4.

L. H. BAILEY.

You will notice from the above, that Prof. Taft has found it even *larger* than the Mikado. Professor Taft says that the plants were on a dry sandy knoll. Now, friends, I am beginning to think that a dry sandy knoll, or a dry gravelly knoll, is a much better place for tomatoes than the ordinary rich grounds of our market gardens. Last season we planted the bulk of our tomatoes right over the best and richest ground; and while they made an enormous amount of foliage, the tomatoes were later, and the greater part of them did not get ripe at all. If you want fruit very early, put it on ground so poor that they will begin to produce fruit when less than a foot high. If our friends who have received seeds of the Ignotum will carefully save their seed from the best tomatoes, there will be a good demand for them another season; and it is altogether likely that no seedsmen will ever be able to sell a very few seeds at a big price, as has been done with many of our novelties when they first came out.

MORE ABOUT BUSH LIMA BEANS.

In response to our order mentioned in our last issue, Thorburn & Co. did send us a packet of lima beans; and 25 of Thorburn's Bush lima beans weigh as much as 75 of Peter Henderson's Bush lima beans; moreover, the 25 beans, when cooked, were a lima bean, and no mistake, and fully as rich and delicious as the King of the Garden lima. Thorburn said that their stock was so limited they could not furnish any except 25-cent packets. We find printed on the envelope the following:

KUMERLE'S DWARF LIMA BEANS.

A novelty of great merit. Originated at Newark, New Jersey. Grows two feet high, branching out in all directions; is very productive, and especially desirable in small gardens, as it does not require any poles. Plant in rows two feet apart and one foot in the rows; one plant only should be allowed to grow in a hill. Per packet of twenty-five seeds, 25 cents.

We have asked Thorburn how many packets he will let us have at 25 cents each. If anybody else on the face of the earth has any of these Kumerle's Dwarf lima beans, we should like to have them stand up and tell us what they know — how many they have, and what they will take for them. It might be worth while to pay a big price for what stock is to be had, even at one cent per bean; for whoever raises a crop of them next season will probably get a good profit on his investment.

QUESTION 110 RECONSIDERED.

SHALL WE SHIP OUR HONEY TO ONE COMMISSION HOUSE, OR DIVIDE IT UP AMONG SEVERAL?

THE COMMISSION MAN A BENEFIT TO THE PURSUIT.

I HAVE had no experience in marketing honey, as this season will be my first in bee culture; but as a gardener I have had twelve or thirteen years of experience. I consider the marketing of honey the same, with this difference: Honey is not a perishable article, and does not have to be sold in one day, or even two or three, as do small fruits and garden truck. I do not think, but know by experience, that taking goods to two or more commission merchants (according to the amount) is a benefit to the shipper, and I believe it the same with honey. Commission merchants have chosen this occupation to accumulate wealth and support, and it would be folly for them to cut down the prices as some of the respondents tried to argue. Honey is something which does not require immediate sale. The larger the price, the more percentage they receive. One point I wish to mention is, that nearly if not all commission merchants have more or less enemies. I know about thirty commission merchants in Buffalo, N. Y., and many more I am not acquainted with. I believe there is not one but that has some enemies, some more than others. If we consign to two or more we have that much benefit. And another great point I look at in the honey line as well as gardening is the amount; for instance, 1000 or 1500 lbs. of honey in one commission house. It would seem a large amount in the eyes of some, but divide it among three or more and it would not be noticed; the same with garden production. If three or four teams came into market with very large loads, the people would exclaim, "Oh my! the market will be away down to-day." Take the same amount in one-horse loads, and the tune will be changed to "A small market to-day. Prices will be way up." Many here have discovered that it is better to go to market with two one-horse loads rather than make a very large two-horse load. Therefore I believe honey should be distributed among the commission houses. As far as my experience goes, I find the commission merchants try to keep a uniform price as far as possible. If every shipper of honey would be careful and sort his honey into two, three, or even more grades, as the case may be, and if, too,

he would paste small labels on each package to indicate first, second, and third quality, etc., and then divide the whole lot of several grades among the commission merchants, he would avoid some of the evils of competition hinted at by some of the respondents to the Question-Box. If Jones or Smith stops at A's commission store, and inquires the price of honey, and then goes to B's shop, Jones or Smith will find the same quality, and then there will be no chance for Jones or Smith to go back to A's store and say they can obtain honey at B's shop at a less figure. The commission merchants are generally up in the morning, and wide awake; they know the quality of goods others are handling. So I think Mr. E. E. Hasty is correct in using for example, the proverb that says, "Don't put all your eggs in one basket."

HORACE F. GRESSMAN.

Water Valley, N. Y., March 4, 1889.

I am exceedingly obliged to you for putting in a good word in favor of commission merchants. There has been altogether too much fault found through the bee-journals and agricultural papers with this class of neighbors of ours. They do have enemies, I know; and many times it is because they are so far away that the one who intrusts them with his produce can not well get acquainted with them as he does with near neighbors. I do not mean that there are not some bad men among them; but if you consult your nearest bank, I think they can tell you almost every time which ones are honest and trustworthy. Sending produce to somebody whom you do not know is like jumping in the dark. I do not quite like your idea of two one-horse loads in place of one two-horse load. The former would take an extra man, and I think your people had better be educated instead of being encouraged in such notions. I believe it is true, that commission men, at least the successful ones, are up in the morning, and wide awake; and if bee-men are not also, they don't deserve success.

SOMETHING ABOUT THE SIZE OF THE BROOD-CHAMBER.

C. J. H. GRAVENHORST'S VIEWS.

I NEVER am more delighted by reading the American bee-papers than at that moment when the author holds with me in an opinion got by carefully conducted experiments. I think there must be some truth in it, if two men, living in different parts of the globe, come to one and the same conclusion, and agree, therefore, with one another. At least I felt so by reading the excellent article in GLEANINGS, No. 1, 1889, by Mr. Doolittle, under the head, "Something about Bee-hives." He says: "By many carefully conducted experiments I found that queens, as a rule, would not occupy more than 800 square inches of comb with brood for any length of time." In order to insure success, and not to get any pollen in the sections, Doolittle allows 200 square inches of comb above the 800 the queen occupied, so that he has 1000 square inches of comb space, or about 1500 cubic inches, as the right size for the brood-chamber, regardless of what style of frame is used. "Of course," says Mr. Doolittle, "the frames one has in use will not always give just the number of square

inches inside of them which is required, but we can use the number which comes nearest to it." That is to say, it matters not whether we allow a few square inches of comb more or less than 1000 for the brood-chamber, but this number is sufficient, and more are not needed. Of course, Mr. Doolittle knows as well as I and many other experienced bee-keepers, that, as we have sometimes dwarfs and giants among men and animals, so we have also small and big colonies in our apiaries, according to the fertility of the queens, aside from other circumstances. Now, I think we are on the right way if we have regard to this, and construct the brood-chambers of our hives neither for dwarfs nor giants, but for standard colonies; that is to say, such colonies as are in the best working order.

As far as I know from what I have read in the American bee-papers, the climate and honey resources at the Home of the Honey-bees in Medina, Ohio, and at the home of Mr. Doolittle, are similar if not equal, as in most sections of Germany, so that our standard colonies need only a brood-chamber of 1000 square inches to remain in full working order. May be that the standard working condition of colonies is not the same in all countries, according to the climate and the honey resources, and that in some sections it may be better to construct the brood-chamber much larger than 1000 square inches of comb space; but that must not lead us the wrong way in our own country.

By using 1000 square inches of comb, Doolittle has in the brood-chamber 50,000 cells for brood-rearing, if one square inch on each side of the comb has 25 cells. I have in the brood-chambers of my hives 51,000 cells in 9 frames. Now, let us see if 50,000 cells are enough for brood-rearing in order to have a good colony in full strength. No one has made more carefully conducted experiments to find out the number of bees in a swarm than the Baron von Berlepsch, so far as I know. He tells us in his book that a strong swarm of bees in a well-conducted apiary contains 20,000 to 22,000 workers. Such a swarm, he says, is in the best working order, if it is doubled so that it has 40,000 to 44,000 bees. If every bee lives six weeks at the time of their utmost working, then the bees will be doubled within six weeks. In order to breed 44,000 bees there must be 44,000 cells, besides the cells for honey-storing. If the queen is very prolific, and deposits only 2200 eggs daily, there would be, within 20 days, 44,000 eggs in the combs; there are in six weeks, more than 88,000 eggs. The hive would be double filled, even if all swarm bees had lived only six weeks. In order to have a colony of 40,000 or 44,000 bees in full strength it is only necessary that the queen deposit 1100 eggs daily during 40 or 44 days. Therefore 1100 square inches of worker comb is sufficient for the brood-chamber, where the climate and honey resources are similar, as at the home of Mr. Doolittle or in Germany.

C. J. H. GRAVENHORST.

Wilsnack, Germany.

It rejoices our hearts to get a word now and then from good friends like yourself, away off across the water; and we feel proud to have you indorse friend Doolittle. If your conclusions are correct, bee-keepers should not spend too much time in hunting up better locations. They should bear in mind that success is not achieved in Medina, in Borodino, nor even away over in Germany, without hard, earnest work.

CHILDREN OF THE KING.

SOMETHING ABOUT BEES AND OTHER THINGS,
FROM SINGAPORE.

BROTHER ROOT:—I have just been reading GLEANINGS; and when I got over to what you had written on Isaiah 55:9 I felt like the man at a family reunion, who met for the first time a distant relative whom he had never seen. As he extended his hand and looked him in the eye he said, "I have never seen you, but I should know you were a Smith, even if I should meet you in London. Here's my hand; we're of one blood." So I was sensible of a thrill of friendly feeling as I read how the hard places in our Father's word used to trouble you, and how our elder Brother made them plain to you in answer to earnest, honest prayer; and I said, "This is one of the family, and I can see the family likeness. So, here's my hand; and though I never saw you, and probably never shall, I want to send you a word of encouragement, and ask you to pray for the Master's work in this distant heathen city.

If you haven't looked to see whose name is attached to this letter by this time, then I miss my guess; but if you haven't, you must begin to ask, "Who is the fellow, and why does he not let us know who he is?" Well, I am a missionary from Ohio, and GLEANINGS is sent to me by friend Dr. A. B. Mason. He knows me and Mrs. M. and both our families; but suffice it to say to GLEANINGS, I am a Buckeye, at work for my King, like a bee for its queen, among the Chinese and Malays of the islands of Singapore.

I have often read your plain, simple expositions or explanations of texts, and have been helped and encouraged; not only by that, but also by the Scriptural way in which you seem to combine business and religion. Let your light shine; you probably could not glorify God more or half so much in any other sphere.

I was a year in Burma, but I have never seen a hive of bees in either that land or this, but heard that some were known of by some one else, and I am inclined to think it a matter of doubt whether any one has an apiary in this part of the world. But there are bees, for a month or two ago I saw a large swarm settle on a big teak-wood tree near our mission house. The Chinese schoolboys (boarders) tried to knock some of the comb down, which they said the bees would make very quickly, but they concluded to let them alone, and the bees went away after a few weeks, I think.

We have perpetual summer here, as we are less than a hundred miles from the equator. But we are so exposed to the sea-breezes that it seldom is over 90° or less than 70°. Foliage is superabundant, but flowers not numerous, yet I have no doubt honey is found to some extent. This I know, we have here some of the finest fruits that grow in the whole world—chiefly sub-acid or sweet—and there is no season, no month, even, when we can not get fruit of some kind in the fruit market or stalls. Oranges, pine-apples, and bananas, abound almost the whole year round. There is now growing, in our compound, coconuts, pine-apples, pomellos, nutmegs, cocoa, mangostines, jack-fruit, rambutans, and durians. The four last are peculiar to this region. The last is called by some writer the "emperor of sub-acids."

It is hard to get acquainted with, but a fast friend.

This, like the jack-fruit, smells from afar. It required a year and numerous attempts to kindle a fondness for either of them, but I am strongly attached to them now.

I left New York in Nov., 1886, and landed in Bombay, India, Jan., 1887. I had a good look at the great city of India, and crossed over the continent to Madras, on the eastern coast. Jan. 28 I plucked the choicest tea-roses from the abounding bushes in the station yard, at the top of the western Ghauts.

I am teaching by day in the Anglo-Chinese school (we have a large school of 250 day pupils, and a dozen boarders), and we hold regular gospel meetings among the artillerymen in Fort Canning, and another among the poor Eurasians in a narrow street called Saliga Road.

Last week several from both these quarters identified themselves with the church of Christ. Our boarders (Chinese boys) are most of them from wealthy Chinese homes. They eat at the same table, and of the same food, that the principal and teachers do. We carefully train them in books, and at the same time teach them about God's word and its contents. Nothing so interests them as Bible stories. The older ones understand the gospel message, pray, and some have said in actions and words, "I want to be a Christian." I saw one of our brightest, most promising boys on his knees before going to sleep, praying to the God of the Bible. We find great joy in doing such work for our Master.

But how often and how keenly do we feel our incompetence alone to undertake the great task of bringing these boys and these people to a knowledge of Jesus Christ as the every-day Savior of men from sin as well as wrath!

Pray for me and the other missionaries, that God may use us in accomplishing the great work, sure to be accomplished in time, of making the kingdoms of this world the kingdoms of God and of his Christ.

R. W. MUNSON.

Singapore, Malaysia, Asia, on Straits of Malacca, Dec. 7, 1888.

Here is my hand, dear brother, with thanks for your exceedingly kind words, especially as I had felt that that chapter of mine was one of my poorest—at least I didn't succeed in telling it so as to give one an idea of the actual experience I passed through in finding great truths where in the first place I had seen only great stumbling-blocks. I wish to emphasize one thought of yours in regard to getting accustomed to new products of the soil. In California the people were, almost without exception, exceedingly fond of pickled olives—that is, with the exception of the "tender feet" as they call them, meaning the new comers. They all assured me that everybody who tasted olives, for the first time, declared they were any thing but pleasant; and while the rest devoured them greedily I was shut out. But I kept tasting them, however, and now I not only find them delicious but nourishing; and if one who goes into a new country gives way to his likes and dislikes, especially prejudice, he will lose a great fund of enjoyment afforded by getting acquainted with such of God's gifts as we have not been accustomed to.—It stirs my heart to hear you speak of the Chinese boys,

and I think yet of that class I had in charge for a brief half-hour in San Buenaventura. I know I am not mistaken when I say that these boys were well started on the up-grade from earth to heaven. With encouragement and looking-after, I am as sure of the outcome as I should be of a crop of corn with plenty of rain and sunshine, and all that can be asked for in the way of soil and fertilizers. May God bless and strengthen you. Such letters as yours will encourage me to make a more hopeful and brighter and better journal than I could otherwise.

HOW TO GET BEES OUT OF CRATES OF HONEY-BOXES, ETC.

ALSO A SUGGESTION IN REGARD TO KEEPING THE MOTH-WORM FROM EMPTY COMBS.

MY bees do not seem to like those queen-excluding honey-boards (?). I hived three swarms in a hive with one in, before I could get one to stay, and then only a half stayed. I let them alone, thinking they had no queen, and would soon die; but when I looked at them a week later they were carrying in pollen. The whole lower part of the hive was filled with empty combs; on top of them I placed the queen-excluder, then another Simplicity body half filled with new white drone comb; on this a crate with partly filled sections from last year. When I went to prepare them for winter I found the crate empty—the top Simplicity body half filled with what looked like nice white honey—and bees—the lower body containing neither bees nor honey. I thought I could not bother to keep them over winter, but would take the white honey from them and let the bees go out at the screen-door along with the other bees. So I had them carried in with the rest, and set on the floor among them. Next day I looked to see if any of the crates were empty of bees, so that they might be carried upstairs, and I found that all the crates and hive-bodies were entirely empty—not a bee in them, and not many bees were clustered on the screen, as there used to be on such occasions, with the exception of that hive-body that had that white-looking honey in. I lifted up the frames and found that, after about three inches of drone comb filled with honey, there was worker comb with a few cells of unhatched brood. All the bees in those twenty or more different boxes had gone in where there was a queen. Now, will bees do this every time? If they will, here is a very easy way to get bees out of sections: Just bring a nucleus with a queen, and put it among the crates, and let all the bees go to her. Perhaps some one has told this before. I do not remember seeing it, and it is *perfectly new* to me.

I had the men carry that hive back to its old stand, and fixed it up for winter, like the rest. Last spring, when I found that so many of my bees had died, I knew that I ought to take care of those combs in some way. But I was too sick and weak, and I made up my mind that the moths would have to eat them. Every week I thought I would get Irving to help me smoke them, or get the beeswax out, or something; but there never was an hour when I could have him, nor a day when I could do it alone. This went on till three weeks before swarming time. Then I went one day to look at them, expecting to be made sick with the sight of

so many worms; but (would anybody believe it?) not a worm was to be seen. I could scarcely believe my eyes. The combs were molded somewhat where the dead bees still clung to them, but there were no moth webs and no worms. I began taking out the combs, and in every hive I found a colony of little black ants. They were mostly in the outside combs which contained some drone combs, and the cells were full of white ant-eggs—or larvæ—Prof. Cook will please tell me which. I took the empty combs then and placed them over colonies, instead of cooking them up, as I expected to do. Now, then, did those ants keep out the moth? or is all nature going to be kind to me after this, and let my things alone? MAHALA B. CHADDOCK.

Vermont, Ill., Feb. 14, 1889.

My friend, your invention is not new. The matter has been several times noticed, and I believe, also, several times mentioned in our journals, that, where a queen is by accident or otherwise carried into the honey-house, all the bees from a great stack of sections will find the queen and cluster around her, and sometimes you can make not only a nucleus but a nice little swarm of bees, and such a swarm will work as well as a natural one. Ants or spiders, if allowed access to empty combs, will keep out the moth-worm. Whether they appropriate the larvæ for food, or whether the moth is afraid of them, we are not able to say.

CAPTAIN HETHERINGTON.

The Largest Bee-Keeper in the World.

BY HIS FRIEND P. H. ELWOOD.

THE subject of this sketch would have gained distinction in any occupation, for nature has endowed him with indomitable will power, coupled with organizing and executive abilities such as would quickly have placed him at the head in any large undertaking. His power of comprehending the whole is no less remarkable than his ability to grasp, at the same time, the minute details of an extensive business.

John Edwin Hetherington was born January 7, 1840, at Cherry Valley, N. Y., where he still resides. He comes of a good ancestry, his father being an educated English gentleman, his mother a member of the old Judd family, of Connecticut. The father dying when the youngest of the three brothers was less than a year old, master John less than three years, the entire care and training of the children fell upon the mother; and the highest tribute we

CAPTAIN HETHERINGTON'S FIRST LOAD OF BEES.

can pay her is to point to the characters developed in her sons. Although all three were in the military service during the late war, they came out as they went in, with spotless reputations, and abstainers from the use of tobacco and strong drink.

The captain bought his first swarm of bees when twelve years old, with money earned for that purpose. The thorough-going business methods of the mature bee-keeper were foreshadowed in the care taken in bringing home his first colony. The old family horse is put before the large spring wagon, and is driven by a member of the family. For the additional comfort and security of the swarm, the hive is suspended in a sheet, the ends of which are tied over a springing pole, while the ends of the pole rest on the shoulders of the two older brothers, who are seated on boards across the wagon-box, facing each other. This extra care seemed necessary for the swarm that was destined to contribute so much toward bringing apiculture from the dark-

he discovered that, while warmer for awhile, this double wall did not allow the sun to drive out the moisture, and the hive soon became damp, and consequently cold. He made six hundred of these, and I think they are as perfect mechanically as hives can be made. Not finding the double wall satisfactory he next put his bees into straw hives, a part of which were adapted to the Quinby size of the Langstroth frame. This was about the time of the commencement of the civil war. These box straw hives were excellent for winter and spring, and well suited to the requirements of the bees at other times. They were not of the usual straw-hive shape, but had flat tops, and were well adapted to boxing. They cost nearly two dollars apiece, and at one time he had about 1400 of them. With the immovable-comb straw hive he adopted a system of artificial swarming that was so successful that he often had not a single natural swarm from an entire apiary. Previous to this he had in use swarm-

CAPT. HETHERINGTON'S HOME, WITH LAST LOAD OF 32 COLONIES IN THE BACKGROUND.

ness of superstition into the full light of modern science. In contrast to this first load we present a picture of the last load of bees, driven by James, the eldest brother. On the one side is seen the captain's residence, while upon the other side is a honey house and shop, with the barn in the rear. At the back of the well-kept lawn are two observatory hives, not shown in the engraving. We endeavored to get in a view of the bee-yard, but it was not possible, for at this time of the year, it is several acres in extent.

The boy bee-keeper had good success, and within five years he had marketed honey by the ton, and had secured an average of nearly sixty pounds of honey in glass boxes from his entire apiary. He was a close observer, and quick to adopt improvements. Before he had been in the business half a dozen years he had perfected a double-walled hive with chamber of confined air between, and had applied for a patent on the same. On thorough trial

catchers for issuing swarms. These were placed before the old colonies, and held the clustered swarms until the apiarist could get around to hive them. It would be an item of interest in apicultural history to have some of these early hives and appliances illustrated. After a trial of the movable frame, the captain found that he could not do without it; but in his trial he made the important discovery that the straw hives with the Langstroth frames did not winter nearly as well as did the others whose combs were built against the sides of the hive, leaving no spaces at the end of the combs. He therefore adopted the newly invented Quinby hive, with closed-end frames. After an experience of years with open and closed end frames he decidedly prefers the latter. No new invention enters the apicultural world but that the captain notices it; and, if valuable, he adopts it. The honey-extractor was his as soon as it crossed the ocean, and he has used it ever since, believing it to be one of the

greatest inventions and one of the most useful articles in the apiary. He believes in producing both comb and extracted honey, in quantities and styles to suit the market. He experimented with comb foundation four or five years after the date of Wagner's patent, obtaining his samples from a Mr. Steel, of New Jersey. The invention came from Germany, as perhaps did also the samples. It was only a midrib, without any attempt at cell-walls, and was a failure, but lacked only the Yankee ingenuity to finish it by giving it side walls, and thus make it a success. The captain has very hopefully followed up this invention from its beginning. He was quite enthusiastic at the time, of receiving the first handsome samples from the Weiss machine; but, alas! he did not then know that it was made of paraffine, nor did he at first observe that the cells were intermediate in size between worker and drone. The queen was slow to use this size of cell except when the sheet was convex, or stretched so that the cells were enlarged, when she very freely deposited drone eggs in them, or where the sheet was concave, so that the cells were diminished in size when workers were reared. Noticing this fact he saw the necessity of making and keeping the cells of the proper size. To prevent sagging he tried cloth, paper, and wood centers, all of which were objectionable. Finally in 1876 he incorporated wires into the wax sheet, and met with complete success. Several years before this, Mr. Quinby and himself had made complete comb of thin tin coated with wax. This was tested in midwinter, the captain bringing bees into a warm room for the purpose; and although the cell bottoms were flat, it was freely occupied with brood and honey. In the manufacture of comb foundation, it was observed that impressing the rhomboidal bases upon the wax sheet would lay bare the wire unless a wasteful quantity of wax was used. To avoid this he left the cell bottom flat, thus also economizing in wax and simplifying its manufacture. Previous to his invention of flat-bottomed foundation he had persistently refused to use natural-base foundation in his honey-boxes, he being unable to make or buy any but that would leave an objectionable fishbone in the honey, and he did not propose to sell to others what he would not use on his own table, or what would injure the high reputation his honey had gained. With flat-bottomed foundation, twelve feet and upward to the pound, he now produces comb honey that, on the average, has a more delicate center than that built wholly by the bees. Last year Mr. Cowan, president of the British Bee-Keepers' Association, looked in vain for foundation or fishbone in Capt. Hetherington's honey. Next day, however, he visited a second-class bee-keeper and found the objectionable hard center in his honey, although he had used no thicker natural-bottom foundation than 10½ feet to the pound. The captain says this foundation is usually worked over, and its base changed; and I have observed that the wax then appears to lose some of its solidity, and becomes more like comb. Certain it is, this foundation makes more tender comb honey than any other we have been able to obtain. Capt. H.'s patent legally covers all kinds of wire supports for foundation, including wired frames, and he should be recognized by the bee-keeping fraternity as the inventor of wire supports for comb foundation. This should be most cheerfully given him, as he has so generously permitted all who wished to do so, to use wired frames.

He receives a royalty upon wired foundation from its manufacturers, the Messrs J. Van Deusen & Sons, of Sprout Brook, N. Y. The importance of this invention is becoming more apparent as time passes, and it must soon take rank as one of the greatest inventions of modern apiculture.

Starkville, N. Y.

P. H. ELWOOD.

To be continued.

UNFINISHED SECTIONS.

DECIDEDLY IN FAVOR OF THEM.

FRIEND ROOT:—Noticing your request in regard to unfinished sections, p. 92, I will give you my experiments and conclusions in regard to the matter. At the close of the season of 1887 I had about 500 unfinished sections on hand. The combs were nicely drawn out, and the sections white and clean. I placed them in crates, *without scraping off the propolis*. I piled the crates up as compactly as possible, and covered them so as to exclude all dust. They wintered in good shape—in fact, they looked as well when I put them on the hives the next spring as they did when taken off in the fall. Thus I was led to believe that they would look as well when completed as those built from new foundation in new sections. Now for the facts: On part of the hives I placed these sections, and on colonies of equal strength I placed crates of new sections. The season opened badly, and the bees were in no hurry to go upstairs. They showed a decided preference to staying in the brood-nest; but those colonies that were supplied with unfinished sections commenced work above first. The sections—that is, the wood—looked rather bad, but the capping was as white as the others. In our market such honey sells as well as any.

The colonies having new sections were about a week behind in starting and capping. There was one exception. One colony completed new sections before the rest had capped honey in the crates. They also cast the first swarm of the season. *They are also the worst robbers I ever saw.* They did not need feeding in the spring, because they fed themselves at the expense of their neighbors. So full of mischief have they been, that we call them the "den of thieves."

From the light of what experience I have had, I believe that it pays to keep unfinished sections. I place one or two in every crate of new sections as a decoy, and am fully convinced that it pays. I shall experiment on the same line next summer, because this season honey came in slowly up to buckwheat bloom, and that may have had something to do with the result.

Hereafter I shall cut my foundation for sections 3½ in. square, as by doing so I get combs built clear out to the wood. I use the 4¼ by 4¼ section.

I did not scrape off the propolis in the fall, as I thought that I could keep them cleaner by handling them as little as possible. You may place me on record as being of the opinion that a colony will complete a crate of unfinished sections sooner than a crate of new sections, even if the latter has a decoy section.

THE WORLD TYPE-WRITER.

I do not wish to close without saying a word in favor of the World type-writer. I am well pleased with mine. After two weeks of practice I can write faster with it than I can with a pen. The

other evening I wrote off a song containing 300 words, in ten minutes, making only five mistakes.

WILLIAM E. GOULD.

Fremont, Mich., Feb. 9, 1889.

It does not seem to me that you hit the point exactly until you come to the concluding part of your last sentence. The question is, "Will bees store more honey in a whole crate of partly finished sections than they will in a crate of new sections filled with foundation with, say, *three or four* partly finished ones in the middle as decoy sections?" We should like to have more facts from actual experience in regard to this latter point.

HOW MUCH IS CONSUMED IN WINTER?

IS IT FAIR TO ESTIMATE FROM OCT. 1 TO MAY 15?

FRIEND ROOT:—In your comments on page 61 to the answers to Question 102, you ask whether your explanation of the widely different reports is not a good one. I don't think you have touched the real root of the matter at all, so please let me give my idea.

The time specified, from October to May, includes time that can not be properly charged to wintering, but includes much time when bees can fly freely, when more or less honey is gathered, and when large amounts of brood are raised. In my answer I estimated the amount of honey in the hive Oct. 1st, less the amount on May 1st, without making any account whatever of the amount gathered and consumed during the time. The amount of honey gathered in the spring before May 1st varies very widely in different localities and in different seasons in the same locality. In Northern Iowa I have known over 40 lbs. per colony, over and above what ever might have been gathered, to be consumed between the dates mentioned; and I remember one season at least where there was fully as much if not more honey in the hives on May 1st than there was Oct. 1st previous. It can easily be seen how impossible it is to get accurate reports to cover so long a time. Again, it is very evident that several of those who answered this question did not do so with reference to the full time covered by the question; in fact, Prof. Cook and Dr. Miller name other dates.

On page 41 friend Doolittle speaks of the climatic changes going on in his section of country on account of the destruction of forest-trees. In the far western prairie States the opposite change is taking place, as more artificial groves are being raised than natural ones are being destroyed. And right here let me repeat what I have already written, that it is useless to expect success in outdoor wintering in the far North, unless the hives are well protected from direct winter winds. A thick grove, not simply a hedge of evergreens or other brushy trees, is best; but I have known success obtained by the use of high tight board inclosures.

Havana, Cuba, Feb. 2, 1889. O. O. POPPLETON.

Friend P., your points are well taken. We have been accustomed to say May 1, because we can not say that our bees are safely wintered until about that date. I do not believe that anybody has overdone the matter of providing windbreaks, very much.

NOTES ON MARCH GLEANINGS.

AND NOW PROF. COOK TAKES FRIEND CORNEIL TO TASK A LITTLE—SEE PAGE 172.

EDITOR GLEANINGS:—I read March GLEANINGS, as I do every number, with much interest. You are to be praised and congratulated for giving us such a rich meal each fortnight.

Mr. Corneil's article, like all of his writings, shows honest, painstaking, conscientious work. His authorities and quotations are excellent and correct, but his conclusions may not be warranted. True, we must have the three kinds of food, and that at frequent intervals. Neither one nor two of the three kinds, carbo-hydrates (starch and sugars), fats, and albuminoids will answer. All *must* be present. But, can we reason that bees must have the same, and at as frequent intervals? Nay, verily, I think not. I have known the Texas horned lizard—usually called horned toad—to live for months with no food. Such reasoning as Mr. Corneil adopts above would pronounce this absurd and impossible. A bear will live in winter, and breathe very little, almost none at all, yet the circulation continues. *Our hearts* would not propel such blood at all. They are not made that way; but the bear's is and does. Now, it is my opinion that bees may pass the winter with no air other than may pass through the hive, and that they may also do well with no nitrogenous food except that which is already in the blood. The bear passes the winter with only the fat of its own body to keep the vital engine at work. May not bees, then, live on pure carbo-hydrates during their winter quiet? I believe so, and, as I said in a recent article sent to GLEANINGS, I shall soon know.

As to air, I kept a colony sealed in ice, at the opening of the hive, one whole winter. It was covered with snow, and wintered exceptionally well. The ice was still intact in spring, when I dug out the hive. Now, there can be no mistake about this. I have tried to repeat the experiment, but without success. It needs a nice adjustment of conditions which I have failed to arrange. Let me say that I froze up the entrance after a very severe winter had commenced. Those bees secured all their air through the hive—doubt it who may.

Sorry, friend Root, that you say science and art are at variance. I say, *never*. In our haste to generalize we assert what is not science. Thus pseudo-science and art, or practice, differ. The chemist said there are no nutritive elements in the silage not in the dried food. That was true. Had he said the dry food is as easy to digest and assimilate as the silage, he would have stated, not a scientific fact, but an untruth, and the cow would have shamed him. We ought all to be careful in our generalizations and statements. Even then the best will make some mistakes.

I like Rambler's bee-dress very much, and Ernest's new Dovetailed hive. How can the board cover be made so it will not twist or warp?

Agricultural College, Mich.

A. J. COOK.

And now, friend Cook, are you not a little mistaken? As soon as I read the sentence, "Sorry, friend Root, that you say science and art are at variance," I carefully scanned my remarks to see where I have even intimated that science and art might be at variance, but I do not find it. All I do find is

this: "If practice and theory should give different results, I would stick to practice." What I meant by it was, that I should at once conclude that science (?) was making a mistake. I know that all of us are often too hasty in drawing conclusions, but I believe that I entirely agree with all you have said in the above.

We are glad you like the Dovetailed hive. As to the cover of the Dovetailed hive, it can not warp, because the ends are driven into longitudinal grooves of the end cleats, which for additional security are nailed. That there may be a twist or wind to such a cover is possible but usually not probable, we think. It should, of course, be kept painted. This cover is similar to the one used by Mr. Heddon, Dr. Miller, and other extensive bee-keepers. If we are correct these gentlemen like them better than any other kind.

KEEPING DIFFERENT KINDS OF HONEY SEPARATE

When Extracting at the Close of the Honey-Flow.

DADANT & SON GIVE US SOME IMPORTANT FACTS IN THE MATTER.

FRIEND ROOT:—On page 126 you ask us our experience concerning harvesting the different grades of honey separately. We wish to say, that we have never tried to leave the entire honey crop on the hives from May till October, but that we do harvest each crop separately. We will ask you to quote from page 436 of the Revised Langstroth: "Some apiarists extract the honey as fast as it is harvested by the bees, and afterward ripen it artificially by exposing it to heat in open vessels. We do not like this method, and prefer to extract the whole crop at once. It is much more economical, for, with our system, one skilled man attends to as many as five or six apiaries during the honey crop, and extracts at leisure afterward, with almost any kind of cheap help. Since honey has now to compete in price with the cheapest of sweets, the question of economical production is not to be disregarded." Now turn to page 444 of the same book. "In localities where there are two distinct honey-crops, each crop should be harvested separately. Thus we always extract the June crop in July, and the fall crop in September." We will add that we never have any mixture, except that of clover with basswood (the basswood crop being of no account here), or the mixture of different fall flowers that bloom at the same time. We will say, also, that we find differences at the same date, in the honey of apiaries four or five miles apart, owing to the greater abundance of one certain kind of blossom in each apiary. Thus we have different grades of honey at one time; and the honey of one barrel can not be taken as a specimen of the honey of another barrel harvested at the same date in a different apiary. The date of granulation also differs, probably owing to the greater or lesser density of the honey. We are not the only ones who have noted this, for Mr. J. M. Hambaugh, of Spring, Ill., has had a similar experience in different apiaries which he conducts according to our methods. CHAS. DADANT & SON.

Hamilton, Hancock Co., Ill.

AMERICAN AND SWISS FEEDERS.

THE MILLER-WARNER FEEDER NOT NEW.

THE following article we copy from the November number, page 215, of the *Revue Internationale d'Apiculture* (French). The translation, by W. P. Root, is as follows:

Similar needs arising in different countries gives birth to the same ideas and inventions, without the inventors having necessarily copied from each other. Such is frequently the case in apiculture, the best instance of which we can cite being the movable-frame hive which Langstroth invented in America, while, but a short time after, Berlepsch, in Europe, transformed the single-barred hives of Dzierzon and of his predecessors, completing the framing of the combs by suspending them, as in the Langstroth model.* The same matter comes up to-day in regard to utensils of far less importance.

After describing and illustrating the Miller-Warner feeder, already given in our columns, the editor, Mr. Bertrand, says:

Now, several years ago there was used in Switzerland a large feeder, invented and manufactured by P. von Siebenthal, in Aigle. It is constructed on the same principle as the American feeder, and does not differ materially. The two troughs are of sheet iron, varnished, and surrounded with wood on three exterior sides. The fourth side is slanting instead of being made vertical, that the bees may have access to the liquid. To prevent them from getting drowned in the troughs, a permanent vertical partition separates the slanting wall, or side, from the trough proper. A space two millimeters ($\frac{1}{50}$ of an inch) high runs between the partition and the bottom of the trough, giving a free passage to the liquid. A sheet of glass, movable, and resting on the two partitions, closes the space between the two platforms above, and retains the heat. See Figs. as below.

A, A, troughs. L, sheet of glass. P, passage for the bees. N, level of the liquid.

The troughs are independent of each other, and can be used separately, and they do not permit of the bees going out, if their dimensions are adapted to the inside of the hive. The sheet of glass being placed on, the cloth covering and cushion are put back. The troughs adapted to the Dadant hives

* Sixty years previously, Francis Huber had conceived the idea of making frames movable by adjusting them to his observatory hives; and Quinby, in the later years of his life, went back to the invention of Huber when he made his hive with fixed frames.

have an interior dimension of about 51 centimeters (20 inches) long and $6\frac{1}{4}$ inches broad. By giving 6 centimeters ($2\frac{1}{2}$ inches) in height to the framework, we obtain about $1\frac{1}{2}$ inches of height which can be utilized for holding liquid. That done, by the opening of the interior wall about 4 liters (a little over a gallon) per trough, or 8 liters per hive, may be put in, and a good quantity will be taken by the bees in a single night.

FOOT-POWER VS. HAND-MACHINES FOR PUTTING FOUNDATION IN SECTIONS.

C. C. MILLER IN FAVOR OF THE CLARK.

ON page 68, Jan. 15, is "A Correction" which I think needs a correction. The last sentence reads, "With regard to the relative merit of the Parker and the foot-power machines, our experience says that the latter work more rapidly and easily, but the Parker does rather *better* work; that is, the foundation is made to hang straighter after it leaves the machine." If, in place of "foot-power," you had said "Gray," I should make no objection; but as "foot-power" includes the Clark, your statement does not agree with my experience. Having had a large experience with both the Parker and the Clark, I feel pretty competent to compare them. It takes so much strength to use the Parker, that my assistant could use it only a short time without stopping. Perhaps, while I am at it, I may as well compare the three, premising that I have very little acquaintance practically with the Gray. Although the Gray may not make quite so good work as the Parker, the labor is lighter, and the Clark takes the least labor of the three; and besides that, it makes *better* work than either of the others. When using the Parker I was troubled by foundation occasionally dropping out of the sections—remember, I use full-sized starters—but it is a very rare thing to have foundation drop out after being fastened with the Clark, although such sections have been trotted back and forth to out-apiaries till a good many have traveled 20 miles.

Friend Root says, that, with the Parker, "the foundation is made to hang straighter after it leaves the machine." I suppose that is true of the Parker as compared with the Gray. The Clark excels the Parker in this respect, in my experience. Indeed, for my use I think the Clark excels in *every* respect. Probably for friend Root the Gray is better, because he uses shallow starters, and has his sections tumbled promiscuously into a basket. I should not want full starters subjected to such treatment. Immediately on leaving the machine I want my sections set upright, either in a super, or preferably in a pile ready for supering.

I suspect that some who have tried these machines will wonder at my strong preference for the Clark; but if they use the Clark *right* they will cease to wonder. The Gray and Parker both depend upon pressure with a sliding motion, to fasten. With the Clark there is to be *no sliding whatever*. All that is needed is a quick swing of the feet, making the presser sink the foundation into the wood, and then the feet come back with a rebound, the whole performance requiring very little strength. I think it would be well if friend Root would change the instructions in his price

list; for if I had to use the Clark as there instructed I would then probably choose between the Gray and Parker.

It remains to be said, that the chief trouble I have had in using the Clark has been in using too much strength, and pressing the foundation so hard as to cut it entirely off, or so nearly off that it was held by a very slight hold. Possibly I ought to say, that, rather than too much strength, the trouble was in having the foundation too warm and soft.

FAILURE OF WHITE CLOVER.

After the severe drouth of 1887, which appeared to kill out a good share of the white clover, root and branch, I watched with intense interest to see what it would do in 1888. As the first green leaves showed, there seemed promise of a fair crop; and when the blossoms opened there was, without exception, the heaviest bloom I ever remember to have seen. The disastrous season of 1887 had so diminished my numbers that I did not average more than 35 to each apiary, and, with such an apparent harvest, and the ground so lightly stocked, I confidently counted on a big yield per colony. The average per colony, spring count, was not quite 12 lbs. I have some doubts whether any great portion of that 12 lbs. was from white clover. I know that a good part of it was not, and I think scarcely any of the stores for winter were from that source. Is it to be, that white clover, like buckwheat and some other things, will have its seasons of failure to yield nectar? or is there any truth in the theory of some, that white clover yields no nectar the first year it blooms after coming from the seed? Although this may be true, it does not seem probable that a whole season's blooming will take place, and no nectar in the flowers. Or is the failure due to electrical conditions, which is equivalent to saying that we common bee-keepers can't tell any thing about it?

Marengo, Ill.

C. C. MILLER.

What we said on page 68 had more direct reference to the Gray machine than to the Clark. When we used to use the Clark we fastened foundation by using pressure and the rubbing motion; but had we used pressure alone, no doubt we should have had better success. We are very glad to get the testimony you give; and, in accordance with your suggestion, we have changed the directions in our price list so as to conform to your method of fastening foundation.

PAINTED VS. UNPAINTED HIVES.

FRIEND DOOLITTLE GIVES US SOME VALUABLE FACTS IN REGARD TO THE MATTER.

AS the season of the year for painting hives is drawing near with us here at the North, and has probably already come to our brethren of the South, I thought a few words on the desirability of our doing so might not be amiss at this time. It will, I think, be admitted by all, that hives look better and will last longer, if painted, than if left unpainted; but I mistrust that \$15.00 a year will sustain more hives if spent for lumber alone than if spent for paint and lumber; yet when we take the looks into consideration, probably there is little difference in favor of either, providing that the bees would do as well in one as

in the other. In this respect, I consider the unpainted hive much better suited to the wants of the bees, and contend that bees will not do nearly as well in painted hives as they will in an unpainted one. Wherein is an unpainted hive better than a painted one? Principally in this, that, if properly covered, it will keep the bees dryer at all seasons of the year, and, owing to this dryness, they are consequently much warmer. As unpainted wood is porous, the moisture evaporates through all parts of the hive, keeping the bees warm, dry, and quiet, thus avoiding an undue consumption of honey, as well as bee-diarrhea. Several years ago I had a number of box hives, some of which were painted, while others were not. I set them out of the cellar about the first of April, in as near an equal condition as could be. In the morning after every cold frosty night, there would be water running out of the entrance of those that were painted, and on tipping them up the combs were found to be quite wet near the outside of them, or next the walls of the hive, while those in unpainted hives were dry and nice, no water ever showing even at the entrance. Those in the unpainted hives increased in numbers faster, and swarmed from one to two weeks earlier, than did those in the painted hives.

"But," says one, "I use corn-cobs, cut straw, forest-leaves, and other absorbents in the top of the hive, to get the moisture out, by letting any excess that may arise pass through them and out at the top of the cover." This will help some as far as the moisture is concerned; but if not done on a scientific plan, it will let out much of the heat by such a direct-draft process, which should be retained in the hive. Even if done properly, I can not help thinking that hives will keep bees better if unpainted, because in this case the moisture passes out of the hive in all directions. Paint is useful only so far as looks and durability are concerned, and is positively injurious as retarding the evaporation of moisture. This is the result which I have arrived at, after years of experience and close observation with single-walled hives, and I believe the damage is greater by far than the cost of a new hive occasionally, where ordinary hives are used.

So far I wish it understood that I have been speaking only of such hives as we used a quarter of a century ago, and not of the chaff hives of the present day. With the advent of the chaff hives came a new era in bee-keeping, and the case with these is entirely different, along this line of painting, than with the single-walled hive. With the chaff hive the moisture is driven through the first wall, which is always of unpainted lumber, just the same as it would be in case of an unpainted single-walled hive, after which it lodges in the chaff or other packing, from which it passes out slowly through any crack or crevice which may exist in the outer shell, and more largely about the joint in the top of the cover and between the cover and the hive. I use a cap or hood six inches deep, on all of my chaff hives, while directly over the bees is a sawdust cushion, which is only four inches thick. This cushion extends out over the chaff packing only an inch or so on all sides, or only sufficient to make sure that all the upward ventilation that can possibly exist must pass through this cushion, and also so as to make sure that no bees can get up into the cap. This leaves the larger share of the chaff walls uncovered except by the cap, so that whatever moisture escapes through the walls of the inner

hive into the chaff can at once pass up into the cap, and out through the cracks of the same, in all mild weather, which it also does to a certain extent on very cold days; yet in zero weather, where the same lasts for several days, I will find the inside of the cap all frosted over, which shows what an amount of moisture is continually passing from the bees. I think that, from this passing-off of the moisture as given above, comes the reason, largely, why bees winter so much better in chaff-packed hives, rather than that the extra protection has all to do with it, as some claim. Bees can endure any amount of cold which we ever experience in the U. S., provided they are kept dry; but dampness and wet they are not able to stand, where cold is added to it. From this comes the reason that bees winter tolerably well in a warm damp cellar, while with the same degree of dampness outdoors they generally perish; or if in such surroundings in any place where the mercury stays below the freezing-point for any length of time, as it necessarily must in our Northern clime. In this we get a little clew to add to the others, which, as a whole, causes our wintering troubles, for I believe these troubles do not rest on any one thing entirely. In accordance with my belief, as expressed in this article, I paint all of my double-walled or chaff hives, and leave all of the rest unpainted, considering that in doing so I am as near right as possible, taking all things into consideration. If any of the readers of GLEANINGS think that I am wrong, a trial of a few hives in each way will convince them which is right.

G. M. DOOLITTLE.

Borodino, N. Y., March 1, 1889.

I have for years, friend D., been pretty well satisfied that what you say is true. An old board with outsides somewhat decayed is warmer, and better for a bee-hive, than a sound board so thoroughly painted that it is as hard and cold, almost, as a marble slab. The old board partakes somewhat of the nature of the walls of the old straw hive. Since you mention it, I do remember of having seen water run out of well-painted hives, in the spring of the year, but I am pretty sure there would have been no such ice and condensation inside had the hives been unpainted, although I never thought of it until you suggested it. I am glad to know that your experience with chaff hives is like my own. Now, somebody is continually improving our chaff hives by making an outside shell of wide boards instead of slats something after the fashion of a corn-crib, as we make them. And while we are discussing this matter I want to say that my opinion has been for some time that the inside of a chaff hive would be better if made of common plastering-lath than as it is now. The principal objection to it is, that it would be more work. Some friend has adopted the plan of making the boards of this inside shell of thin lumber, perforated with holes; and as this was discussed in the journals some years ago, I wish the friend who had the idea would tell us how it answers for a wintering hive. Of course, if we make the outside exposed to the weather, with narrow slats, we must have these slats beveled on their edges, so as to let the water run down the outside as much as possible, instead of going through and wetting the chaff.

HEADS OF GRAIN FROM DIFFERENT FIELDS.

THE TARANTULA; SOMETHING MORE CONCERNING ITS HABITS.

ALLOW me to correct your mistake in regard to tarantula nests. It is only a hole in the ground, without a cap, and the web very light. The nest you speak of is that of the trap-door spider, which is a much smaller spider, and without the hair. Tarantulas are both black and brown in color. The males have small bodies and very long legs; the females have longer bodies. I have captured a great many while in California, and killed and mounted some for sale, while working at my trade of taxidermist in Pasadena. To capture them, all that is necessary is plenty of water, a pair of large tweezers, and plenty of small pasteboard boxes; for if they are put together they will kill one another. I have frequently brought in 100 or more in half a day's hunt with a horse and buggy. When you find the location, a dozy clay soil, you pour water in their holes and the spider comes up to see what is the matter. You then catch him with the long tweezers, and box him. I killed them with chloroform, and then prepared with arsenic. I mounted some 500 while in California last winter. I sent you a fine specimen, if you remember.

Williamson, N. Y., Feb., 1889. T. G. ASHMEAD.

Very likely you are right, friend A.; but the boy who brought me the nest, with its velvet lining and neat little trap-door, told me, if I remember correctly, that it was the nest of the tarantula.

STARTING BEES INTO THE SUPERS WITH SECTIONS OF HONEY; WILL ITALIANS FILL THE SUPERS AS READILY AS THE BLACKS?

In GLEANINGS of Feb. 1, page 91, I notice an experiment of Elias Cole, in regard to the best thing to get bees to work in the supers as soon as put on. Last season I put nothing in the sections but narrow starters, until about the 1st of August, and the bees seemed loth to work in them. One day in taking off honey I put one section full of honey in each row in the super, and the next morning the bees had nice combs built on each side of the honey, so I did that way until the close of the season; and the result was the same in every case. I think empty combs would have done as well, but I did not have them.

Is there any strain of Italian bees that will work in sections, equal to the blacks? From my experience, I say no.

243 BUSHELS OF JAPANESE BUCKWHEAT FROM 5 BUSHELS OF SEED.

From 5 bushels of Japanese buckwheat that my brother bought of you last summer he had 243 bushels. It was sown on sod land at that.

C. B. JACKSON.

Eau Claire, Wis., Feb. 12, 1889.

Friend J., if you fixed a lot of hives with sections containing just starters, and none with unfinished combs for decoy, you certainly neglected to follow the instructions of the journals and the text-books. No wonder your bees didn't commence work. You probably lost a good many pounds of honey by the operation. I think the A B C book, as long ago as when it was first written,

recommended taking a few sections from a hive that had already commenced work; and as it is some bother to get the bees off, I advised taking the section, not only with the comb and honey, but bees too. With such a hint as that, almost any colony with sufficient strength will commence to work as you have described—that is, when the other colonies are working in sections.—I suppose it is true, that black bees, as a rule, go up into supers more readily than Italians. They also very often put all their honey in the sections, and then starve to death if the owner does not look after them, while the more prudent Italians would have a supply in the brood-nest before they commenced in the supers.—So your brother made a pretty good thing of the Japanese buckwheat, did he not, friend J.?

CHAFF PROTECTION FOR SURPLUS BOXES.

My principal honey harvest is from the heather, which comes in about the middle of August. From the variableness of our climate at that season of the year we have difficulty in keeping the bees in the super at night. I make an outer case, for wintering, about three inches all over larger than my hives (the Simplicity), and fill up with chaff. Now, would you advise this outer case to be kept on during our honey season? How would this compare with your chaff hive, mentioned in your A B C?

Now that you have done California, why not link your arm in that of Dr. C. C. Miller and come over and see your cousins "across the pond"? We have a cold climate in the north here, but you would find warm hearts before you. W. STOKES.

Carr Bridge, Scotland, Feb. 2, 1889.

Friend S., we certainly would advise you to keep the outer case on during the honey season. Most of our colonies are in chaff hives, and our experience has been most emphatically that chaff protection around the surplus boxes is certainly a good thing. According to our experience bees are more apt to build comb in chaff-protected supers than in those not so protected, and they are more inclined, also, to enter the boxes. The reluctance of bees to enter the surplus apartment might, we think, sometimes be overcome with chaff packing around the super. Thanks for the kind invitation.

BASSWOOD LUMBER; HOW TO GET IT CLEAR AND WHITE.

We have commenced making sections. We find considerable of our basswood is colored, and do not know how to account for it. The most of the stuff was cut this winter, and we know most of it was white and nice when sawed. We shall be glad to have any information you can give us.

Riverton, Va., Feb. 18, 1889.

J. SLACK.

Friend S., it takes years of experience, or, at least, it has taken us many years, to learn the knack of getting perfectly white basswood when dry. In the first place, the trees should be cut in cold weather, before the sap starts in the spring. The logs should be taken to the mill and sawed just as soon after cutting as possible; then the lumber must be sticked up right away, well spaced out, with good slant, well covered, in the open air. If these directions are strictly followed, you will have nice lumber, if you use nice timber to start with. It

takes four or five months for the timber to season properly. In fact, it had better not be used for almost a year after it is cut. We anticipate our needs a year ahead in getting basswood lumber, and have to keep a stock of from \$5000 to \$10,000 worth in our yard all the time.

FEEDING AT ENTRANCE DURING THE DAY.

Please tell me if it would do to place a feeder at the entrance of a hive through the day, and cover the feeder with a box, and have it so arranged that the bees can get to the feed, but not out of the box. My bees get wild when I feed them a little.

Muncie, Ind.

E. W. HITCHENS.

Friend H., you could feed bees in the manner you propose, but we would not advise it. Better put the feeder on top of the brood-frames. If there is not space under the cover, put on an extra super or brood-chamber. Feeding at the entrance during the day is dangerous business, especially for beginners. We sell an entrance feeder, to be used during the day, but after all we regard it safer to use an entrance feeder at night, or, better still, put it upon the brood-frames as stated. Bees are apt to rush out of the hive in excitement if fed during the day, when no natural stores are coming in.

A SHRUB WHICH BLOSSOMS WITH THE SNOW ON THE GROUND.

Foraythia viridissima is a hardy early-flowering shrub, introduced some years ago from Japan, where it is said to blossom on and under the snow. I have seen it flower more than once on top of snow one or two feet deep, in this country. It seems that, while the ground is covered with snow, the sun causes the buds to burst, partly by reflection I suppose. Some people call it golden-bell. The branches are thickly covered with yellow flowers, which it produces any way; and if it is no honey-plant, I should say the pollen would be very acceptable where enough of it could be planted for bees to gather it. The shrub is hardy, very attractive, and not very fastidious about soil or location, but blooms, often, when nothing else can be found, like the witch-hazel in the fall. Perhaps others will send in their experience.

Sandusky, O., Feb. 3, 1889.

F. J. M. OTTO.

Friend O., where can this plant be obtained? Is it found in the catalogues, or does it grow in the woods like witch-hazel? I do not suppose it would be worth very much to the bees, as it blossoms almost too early, but it might be interesting as a curiosity.

A SUGGESTION FOR THE CLARK SMOKER.

I have bored an inch hole opposite the large end of the cold-blast tube in the Clark smokers, and over that hole I fastened securely a 2-inch tin screw cap, of the flat variety (not the kind that have a convex base), so that we can more easily clean out the tubes that are sometimes so liable to choke up with soot. Please try this feature on an old smoker that needs cleaning. The spring need not interfere, as the center of the tin cap need not be exactly over the tube. It is true, there is a patent on the caps, but the caps do not know it or say so.

Terre Haute, Ind.

H.

When we had the old blast tube we had thought of putting on the feature you speak of; but since enlarging the tube, such a pro-

vision is not so necessary. It might prove a convenience, but the advantage we think would hardly warrant the expense.

AN EYE-WITNESS TO THE QUEEN'S SEPARATION FROM THE DRONE AFTER MATING.

On page 92, Mr. E. A. Pratt speaks of queens and drones mating. I was going out to my bees one day, when two bees came whirling down in front of me and fell on to a pumpkin leaf. It proved to be a queen and drone. The drone acted as if he had been stung by a worker. He held fast to the leaf with his feet, and the queen kept whirling over and over, about as a fly would if caught in a spider's web, until she freed herself, then she flew out of sight in an instant, and the drone remained where he was on the leaf, but showed life for only about three minutes.

S. R. FLETCHER.

Onawa City, Iowa, Feb. 19, 1889.

Very good, friend F. We now have the whole thing from beginning to end, and I think that others have in times past reported pretty nearly the same thing you witnessed, so that we are able in our text-books to describe the operation from beginning to end, providing it always happens after about the same fashion.

CHAPMAN HONEY-PLANT SEED—HOW TO GET IT OF THE GOVERNMENT.

As I see some complaint in GLEANINGS, on page 134, by A. L. Lane and you about the distribution of the Chapman honey-plant seed by the Department of Agriculture at Washington, I want to say that I too read the notice in GLEANINGS last spring, and I at once wrote to Hon. Norman J. Colman, Commissioner of Agriculture, at Washington, for some seed, and soon got a little package of the same. I sowed some, and almost every seed came up all right. Some plants had, by fall, leaves 28 inches long. I believe if Mr. Lane had applied to Hon. Norman J. Colman, Commissioner, for the seed, instead of to his Representative, he would have received some.

JACOB RUCH, JR.

Gruetli, Grundy Co., Tenn., Feb. 21, 1889.

DISTURBING BEES IN COOL WEATHER; CLOSING THE ENTRANCE.

Referring to Question 90, disturbing bees in cool weather, please insist that all of your A B C class, and others whom you can influence, do make it a point, when examining bees while weather is too cool for them to fly, to close the front entrance of the hive with a cloth or block before opening the hive, removing the cloth or block when the hive-cover is replaced. You may try the plan in your dwelling when the weather is just right. One door or window may be open to advantage; but open a door opposite the one already open, and you can feel the draft, if you do not see the point. I hoped to read of this feature long since; but no paper that I have seen advances the advantage of shutting off the draft.

Terre Haute, Ind.

SALT AS A FERTILIZER.

Have any of the readers ever tried sowing salt on buckwheat ground? What was the result? I am contemplating sowing about 24 acres of Japanese buckwheat. I can get the salt for \$3.50 or \$4.00 per ton, and the ground is heavy loam. I have tried it on common wheat, and I think it makes it plumper and whiter.

All my bees are in splendid shape up to date. I have 10 in chaff hives on their summer stands, and 22 in the cellar under the house. They were put in Oct. 20, and are as nice as a new pin.

Jackson, Mich., Feb. 6, 1889. W. D. SOPER.

I would by no means think of applying salt at the rate you speak of, unless I had first tested it on a small scale. Now, please bear in mind that you can not test salt, phosphate, bone-dust, guano, or any thing else, unless you put it in your field in strips, leaving a strip without the fertilizer alongside of one with it. If there is a decided improvement in the fertilized strips, clear through the whole length, it amounts to something. Then you are ready for the question, "Does it increase the yield enough to pay the cost?" I am sure there is a good deal of blundering in the dark in this matter of fertilizers.

DR. TINKER DISCUSSES MR. SHEPHERD'S ZINC; SEE PAGE 11, JAN. 1.

Friend Root:—Mr. Shepherd's zinc is new, so far as I know, but the perforations are the exact length and width of those I have in my zinc. His zinc has no advantages over the usual style of perforating, as you state in the foot-note. Mr. Shepherd is also mistaken in supposing that more openings can be made in a given piece of zinc by perforating his way. The strips of zinc I use in my wood-zinc honey-board are only $\frac{3}{4}$ of an inch wide, and yet eight of these strips (the number used in a honey-board) have 352 perforations. Mr. Shepherd's zinc is one inch wide, and eight strips of the same length would have 372 perforations, or only 20 more than my honey-board now contains. But strips of my zinc one inch wide would have three rows of perforations, as you will see by the inclosed sample, which would make 528 perforations in the honey-boards, or 156 more than Mr. Shepherd's zinc would have in the same size of board.

Strips of zinc one inch wide, if used between wood slats spaced $1\frac{1}{8}$ inches, as they should be, would not leave enough wood in the slats to properly support the zinc, as you well observe. The wood slats in my honey-board are a little over $\frac{7}{8}$ of an inch wide by $\frac{3}{8}$ thick; and used with strips of zinc $\frac{3}{4}$ of an inch wide they make a strong honey-board; and if the zinc has two rows of perforations there will be all the perforations necessary for the largest colony.

I presume Mr. Shepherd's perforator is made of wood, carrying a punch and die, as it would cost about \$75.00 to make a good iron machine to go by a belt. The wood machine can be made to do very fair work at the start, but the dies are soon spoiled. Good perforated zinc is now so cheap that I can not think it would pay any one to make a wooden machine.

DR. G. L. TINKER.

New Philadelphia, O., March 2, 1889.

HOW TO KEEP HONEY FROM CANDYING; PERFORATED ZINC NOT A PREVENTIVE OF SWARMING.

Can you tell me of a method to prevent honey in the comb, and also extracted honey, from candying? Can swarming be successfully prevented by placing perforated zinc before the entrance so as to keep the queen from flying?

S. HOWE.

Clarence, N. Y., Mar. 4, 1889.

Candyng can not be prevented entirely, but you can do a good deal toward it. See what is said in the A B C book, especially in

regard to extracted honey. If it is in the comb the temperature should not be allowed to go down to freezing. Swarming can not be prevented by the use of perforated zinc, although it may be thwarted for the time being. The zinc simply prevents the queen from going out with the swarm. The latter, in her absence, will usually return. But it is not advisable to let the bees make a second attempt. Trying again, and failing, they will be pretty apt to destroy the queen. The zinc is a convenience while you and the rest of the family are away.

BREAKING OF ONE-PIECE SECTIONS, AND HOW TO PREVENT WHEN THE TIMBER IS TOO DRY.

Last spring, after I had put on the first sections, I carried a crate containing about 350 to the attic, under a slate roof. Temperature was 110° to 130° during the clear days. When I came to use them, several weeks later, they were so dry I could not fold them without breaking. I carried them to the cellar for a day, when I could fold without a single break.

A NEW FORAGE PLANT.

The *Am. Agriculturist* for Feb. tells of a new forage plant called "serradella." Dr. A. W. Thornton, Washington Ter., speaks of it as being valuable for bee-pasturage. It is planted about corn-planting time, and blooms from July 1st to frost, so it can be cut twice. It is equal to timothy hay for feeding.

W. W. KULP.

Pottstown, Pa., Feb. 11, 1889.

Your ideas in regard to handling sections to make them fold up are good, friend K.

ITALIANS BEST, HYBRIDS INFERIOR, AND BLACKS POOR.

I have 50 strong colonies of bees—blacks, Italians, hybrids, and albinos. The Italians are the best honey-gatherers I ever saw. For Texas they are the bee. If honey is to be had, they will surely get it. My best Italian colony gave me about 90 pounds of comb honey. My best hybrid colony gave 50 pounds of comb honey; best black colony, 35 pounds of comb honey. All of them had the same showing. The flow from the horsemint lasted about 30 days, being the only good flow from that source since 1884.

Lexington, Tex., Feb. 12, 1889. W. S. DOUGLASS.

DECOY HIVES; BUILDING UP AN APIARY BY MEANS OF.

I have been reading your A B C, and was attracted by your article on "Decoy Hives," under "Swarming." I am but a novice, and have had very little experience in bee culture, and am indebted to Mr. F. Danzenbaker and your A B C for what little I know. In 1886 I noticed about 100 bees flying about our barn in swarming season, and immediately put an old bee-hive there. Next day at ten o'clock there was a large colony; that afternoon there were a few more bees around the gable end of our house, and I put a hive there. Meanwhile I had put another hive in place of No. 1. (I will designate hives by numbers.) The next day I had a second swarm in No. 1 and one in No. 2. They had crossed the Delaware, which is two miles wide at this point, and had half a mile from our place to the river; and as it is a marsh for fully a mile to the first house on the New Jersey side, they must have flown at least $3\frac{1}{2}$ miles. Subsequently I had two more swarms from across the river, and two more from this side, all outside of

my small apiary of 14 hives at that time. There was a man who followed swarm No. 1, from the river-bank up to our barn, and saw them go into my hive. Now, as I was watching for them, and had made preparations for them, and as he had no hives to live them, whose ought they to be? I offered them to him; but when he saw my preparations for them he would not take them. He is my cousin's husband, and I afterward got two swarms off the place from him, so we are good enough friends, but I don't know who had the legal right. In 1887 I took three more, and one in 1888, by using decoy hives. WM. S. SLOAN.

Claymont, Delaware, Mar. 3, 1889.

Friend S., your facts are very valuable. From what you say it would seem that bees have a special fancy for selecting special localities for migrating. What it is that attracts the new swarm, or decides them on going in a new direction, is not very fully understood, and we should be very glad of some facts bearing on this point. If we were sufficiently well posted in regard to their habits and instincts, perhaps we might induce them to do the swarming themselves and go into hives already prepared.

IS THERE ANY CURE FOR SPRING DWINDLING?

Do you know any cure for spring dwindling? If so, please let me know. My bees are all getting along finely except two colonies which keep flying out in cold days, and dying. They are in 4-inch walled chaff hives, good and strong, with plenty of bees and plenty of honey. What ails them? What can I do to cure them? C. S. JOHNSTON.

Emilonton, Pa., Feb. 21, 1889.

Friend J., no one is prepared, that I know of, to say exactly what causes spring dwindling. It may possibly be somewhat dependent on the queen, or it may be some sort of disease that afflicts certain hives. The fact, however, that most of the veterans have succeeded in getting along without any of it for a good many years, would indicate that management has much to do with it. Have those two colonies that keep flying out in cold weather exactly the same stores that the rest have?

BEES GATHERING BITS OF OLD WAX.

Let us have facts—real, certain, unmistakable facts: There can be no science without them. Last summer, on the 2d day of July I transferred a swarm of hybrid bees from a post-oak log, in which they were found, and put them into a movable-frame hive, and filled only one frame with comb, and stuck some pieces to the under side of the other frames. The bees from that hive would gather the comb that was left sticking to the old log, and carry it into the movable-frame hive, and build comb on the pieces which I attached to the top of the frames. I watched them, and I know whereof I speak. Has anybody else ever known such? The bees would gather it on their legs like pollen, in the heat of the day, when the wax was very soft. Don't think I am mistaken, and say it was propolis, for it was not, and they built comb with it. You could readily tell the comb they made of the wax thus gathered. E. ANDERSON.

Comanche, Tex.

Friend A., the fact that you record, in regard to bees carrying wax, is a matter of common observation. When they have

nothing else to do, and the weather is suitable, they very frequently do this if they can get access to wax.

REPORTS ENCOURAGING.

FROM 37 TO 76 COLONIES, AND 8620 LBS. OF HONEY; A GOOD REPORT.

FOUR years ago I sent my winter's loss to GLEANINGS; but this time I will send my last summer's gain. From 37 colonies, commencing with basswood, I extracted 6500 lbs., and secured 200 lbs. of comb honey. I have on hand for spring feeding 240 large combs that will weigh 8 lbs. to the comb, making 1920 lbs., or a grand total of 8620 lbs., and increased to 76 colonies. They are wintering all right yet. I did not pay out a dollar for help. My boy of 9 and girl of 11 years and I did all the work, except some very light that my sick wife helped on; and the saddest of it all is, she has left us since then, and gone to that home beyond. We took care of a garden of 13 lots in 3 different blocks. We work six days in a week, and serve the Lord in our humble way on Sunday.

QUANTITY AND QUALITY; ARE THE REPORTS OF LARGE YIELDS AN INJURY TO THE CRAFT?

Mrs. L. Harrison says those who report such large yields of extracted honey, and claim to produce it so cheaply, are an injury to the craft. As I have done both for the last 7 years, please tell the readers of GLEANINGS of the quality of that 1100 lbs. I sent you last summer; also of the two samples I sent to-day, for I pride myself in that I raise as good honey as the best in this part—at least I am no old bee-keeper. Ten years ago I knew nothing about bees. I had never seen a swarm in the air nor in a tree. I could not tell what a queen or a drone was. In the winter of 1880 a neighbor gave me two box-hive swarms. I have sold and lost a good many swarms since then. The Bible, GLEANINGS, A B C, and W. H. Stewart, of Orion, have been my guides every day since. F. C. SNYDER.

Orion, Wis., Feb. 26, 1889.

Friend S., we are very glad indeed to find that you pulled through after your winter's losses, and have made such a good record. Such a report is especially refreshing after such a season as 1888, when so many of the reports were discouraging. You see you have secured toward 200 pounds to the hive, and at the same time more than doubled. Your 1100 lbs. of honey was excellent; and one of the samples you sent us has something remarkably fine about it. I should say that at least a part of it came from red clover. Right glad am I to see that you have no hesitation in placing the Bible first and foremost among your friends and helpers.

FROM 55 TO 105, AND 4500 LBS. OF HONEY.

We commenced with 55 swarms—50 good, the other five very weak, and increased to 105. We sold one swarm, united some, and now have 96 in the cellar. Five more are now sold, to be delivered in the spring. The temperature has averaged 48—a little too warm. The bees seem uneasy most of the time. I can not remember of as mild a winter, and I have lived here for 32 years. We took off 4500 1-lb. sections—2000 basswood and clover, the rest golden-

rod and wild sunflowers. The honey is the nicest fall honey we ever produced. We sold 500 lbs. or more, cut right out of the brood-frames. The light honey brought $12\frac{1}{2}$ —2000 lbs., \$250. The dark honey brought 10—3000 lbs., \$300. Six swarms of bees brought \$15.00. All sold within 12 miles of home. We did not have enough to supply the demand. We think we have reason to thank the Master—don't you?

E. R. A. BRAINARD.

Postville, Iowa, Jan. 21, 1889.

To be sure, friend B.; and it rejoices my soul to see so many of the readers of GLEANINGS indicate even in their reports that they recognize in their work the all-wise Ruler of the universe.

1047½ GALLONS OF HONEY; THE LAST SEASON THE BEST FOR YEARS.

Last year was the best for honey we have had here in many years; 120 colonies made for me 1047½ gallons of honey; average per colony, 8½ gallons.

Padgett, Ala., Feb. 9, 1889.

B. B. TONEY.

Well done again, friend Toney. This makes another tiptop report for 1888.

11½ TONS OF HONEY LAST SEASON, AND 29 TONS FOR THE PAST THREE SEASONS.

My honey crop this season was 11½ tons, and for the past three seasons 29 tons. When you come to visit friend Freeborn next summer, just drive around this way, and I think we can show you a few "points" in our management worth seeing.

Mauston, Wis., Feb. 19, 1889.

FRANK MCNAY.

3500 LBS. OF HONEY FROM 32 COLONIES THE FIRST YEAR.

Last year I bought 32 stands of bees at wheat harvest, and during the fall I harvested about 3500 lbs. of fine extracted honey, and increased to 51 by natural swarming. They are all in very fine shape.

JOSEPH TRINDLEY.

St. Peters, Mo., Feb. 20, 1889.

REPORTS DISCOURAGING.

NOT ENCOURAGING FOR NEW SOUTH WALES.

WE are having a very bad season here this year. Last season I put an Italian swarm into a hive of comb foundation, Nov. 1, and on Dec. 8th I extracted 50 lbs. of honey from it, from white clover. This season, no signs of swarming yet. The Italians are the only ones getting honey. The blacks make scarcely enough to live on. When I say a bad season here, I mean in the "New England District of New South Wales."

JOHN S. RUTTER.

Armidaale, Australia, Jan. 7, 1889.

NOT ENCOURAGING FOR AUSTRALIA.

We regret to say, that this season the bees have not done any thing worth speaking of, and our trade in supplies has been correspondingly small. Reports are, however, improving, and men have told us of "pure Italians" (?) being found "in the bush" as we call it—that is to say, building in trees, etc., wild. At any rate, swarming has commenced at last; and if we have a long summer we might make up for some of the trade which we might have done if the season had been more propitious.

Sydney, Jan. 21, 1889.

HEBBLEWHITE & CO.

NOTES AND QUERIES.

We solicit for this department short items and questions of a practical nature; but all QUESTIONS, if accompanied by other matter, must be put upon a SEPARATE slip of paper with name and address.

TO TRANSFER IN WINTER.

IS it possible to transfer a colony of bees from an old-fashioned box hive to a hive with movable frames, in the winter? They have no honey in the old hive, and I wish to transfer them for feeding.

JOHN HOBBS.

Red Hook, N. Y., Feb. 6, 1889.

[Experts have done it frequently, but a beginner should not undertake it. The better way would be to pry off part of the top of the hive, and feed them as you would ordinarily a colony in a movable-frame hive. If they pull through all right, you can then transfer them during apple-bloom next spring.]

OAT HULLS INSTEAD OF CHAFF.

I am putting up a few chaff hives, but I have no chaff to fill them with, and I'd like to use them this summer. The question is, Would oat hulls do to fill them, instead of chaff? Don't you think that would be a good substitute?

J. L. EDWARDS.

Oxford, Ia., Feb. 7, 1889.

[Oat hulls might answer for a packing; but if you can possibly get chaff we would recommend you to use it instead. For further particulars, see A B C book on "Wintering," a prospectus of which we inclose you.]

HOW LONG FROM A START WILL IT TAKE FOR FOUL BROOD TO INFECT THE WHOLE HIVE?

How long would it take foul brood to get under such headway in a hive containing 12 Gallup frames that every comb should be affected more or less—say from $\frac{1}{2}$ to $\frac{3}{4}$ of all cells used in brood-rearing being affected?

D. W. C. MATTHEWS.

Ypsilanti, Mich., Feb. 7, 1889.

[After foul brood has made its appearance in a few cells in a hive, if neglected by the apiarist that long, it will take only about a week or ten days for it to affect every comb. In two weeks every cell of brood will be rotten.]

COFFEE-CANS FOR EXTRACTED HONEY.

Will large tin cans that roasted coffee comes in, holding 50 lbs. of coffee and 16 gallons of honey, be stout enough to ship honey in? Cans are boxed.

Madison, Ga., Feb. 12.

R. H. CAMPBELL.

[If the coffee-cans are securely soldered I should think they might answer; but as they are manufactured for shipping coffee and not for honey, which is so very much heavier, I think you had better test them carefully before risking very much honey in them.]

BEEES ALL "FROZE;" HOW TO START ANEW.

Can a person start up a swarm of bees by getting a queen and a pound of bees? Mine all froze. I should like to start again.

M. J. BOWLES.

Sexton, Ind., Feb. 4, 1889.

[With a pound of bees and a queen you can make a very nice start. Where one has lost all his bees, this is the best way to begin anew. It certainly is the cheapest.]

40 BUSHELS OF JAPANESE BUCKWHEAT FROM 1 PECK OF SEED.

We have received GLEANINGS regularly, for which we thank you. We are well pleased with it. The peck of Japanese buckwheat I bought of you last year I sowed on $\frac{1}{2}$ acre of ground. It yielded 40 bushels by measure.

J. N. BUZZA.

Kossuth, Pa., Feb. 18, 1889.

197 BUSHELS OF JAPANESE BUCKWHEAT FROM ONE POUND OF SEED, IN TWO SEASONS.

I was well pleased with the Japanese buckwheat I got from you. I got 1 lb. in 1887, and I raised three bushels. I sowed this, and got 197 bushels from four acres, and did not use any fertilizer or manure.

Vose, Pa., Feb. 25, 1889.

G. A. CONRAD.

5½ BUSHELS OF JAPANESE BUCKWHEAT FROM 6 LBS. OF SEED.

I sowed 6 lbs. of Japanese buckwheat last spring, and harvested 5½ bushels, and that on thin land without manure. I think it is the best buckwheat in the world.

T. R. CANADY.

Roark, Mo., Jan. 23, 1889.

THAT CALIFORNIA TRIP.

I have been much interested in the report of your trip. I was over much of the same route the year before. I am now moving out there. If you did not visit Pomona, you missed one of the nicest places in Southern California. The author of "Blessed Bees" lives at Pomona.

Green, N. Y., Jan. 17, 1889.

L. E. ST. JOHN.

PREVENTING INCREASE; A QUESTION.

How would the following method of preventing increase succeed? Follow Dr. Miller's plan of giving plenty of room in the sections; hive all prime swarms that come out, and prevent after-swarms by some well-known method; the following season, unite down to the original number at the beginning of the honey-flow, using the empty hives and combs to repeat the operation?

A. C. BUGBEE.

Lochiel, Ind.

[Your idea of uniting in the spring, so as to have your colonies all exceedingly strong just before the honey harvest opens, is one that has been considerably discussed, and some very successful honey-producers tried the method years ago.]

FRAMES PARALLEL OR AT RIGHT ANGLES TO THE ENTRANCE; WHICH?

Will bees do better to enter at the side or ends of frames in a house-apiary? I think I prefer to have entrance at sides of frames, but am not certain that it will do so well.

R. E. MASON.

Westminster, S. C., Feb. 19, 1889.

[Friend M., we do not think it is very material whether the frames are parallel with the entrance, or at right angles with it. We rather prefer the latter arrangement. Theoretically, the bees can better ventilate their hives during summer; but practically, there does not seem to be very much difference. Numerous tests have been made both ways, and there was no appreciable difference in the result, either in the amount of honey secured or in its proper evaporation.]

TWO OR THREE THICKNESSES OF PAPER INSTEAD OF CHAFF.

I come to GLEANINGS for advice. Another bee-keeper and myself conceived the idea that we would make several hives with double walls with two or three thicknesses of paper between, believing that paper is a non-conductor of heat or cold. Now, I want to know what would be the difference between them and chaff hives.

WM. BARCLAY.

Harmony, Ind.

[It is claimed by some, that two or three thicknesses of paper around the brood-nest, in between the outer shell, is equal to 3 or 4 inches of chaff—among them Francis Danzenbaker, of Claymont, New Castle Co., Del. As for ourselves, we can hardly see how the paper can be equal to chaff. It may be as warm, but it will not absorb moisture as well. G. M. Doolittle's article in the present number tells pretty nearly why chaff will be better than paper.]

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

All queries sent in for this department should be briefly stated, and free from any possible ambiguity. The question or questions should be written upon a separate slip of paper, and marked, "For Our Question-Box."

QUESTION 112.—a. What is the largest number of L. brood-frames you allow a colony at any time? b. If you vary the number, say when you allow the most. Say whether you mean for comb or extracted.

Nine or ten frames of the large Quinby size, both for comb or extracted.

DADANT & SON.

a. Eight is the largest number. b. I never vary the number, either for comb or extracted honey.

GEO. GRIMM.

Eight. This is my number in brood-chamber. For extracting I add a second story, making sixteen frames.

A. J. COOK.

Working for extracted honey, a. 24, three stories high, eight frames each, in the height of honey-gathering, with extra strong colonies; ordinarily 16.

R. WILKIN.

For comb honey, 8; but I winter outdoors on two sets of 8 frames, one set above the other, and the upper set full of honey; for extracted honey, three tiers high, 8 frames in a tier, 24 frames in all.

E. FRANCE.

I allow 19—10 in brood-chamber and 9 above—for extracted honey. For comb honey, 8 frames below is generally preferred. The surplus should not be added before the bees begin to gather in the spring.

P. L. VIALLOIN.

a. 27 is the largest number I ever used at one time. b. I allow the most when the most are needed; for extracted honey I furnish the colony with all the combs or foundation they need, and tier up, using no honey-board.

DR. A. B. MASON.

a. Eight for box honey. b. In the early spring, especially if the colony is weak, I contract to five or six frames, and expand the brood-chamber as the season advances; but I do not contract during the honey-flow, to force bees into the boxes.

MRS. L. HARRISON.

We use a frame 10½x16 inside. Before putting on boxes we usually build them up to seven frames. When we had black bees we built up to eight. We usually reduce the number by one not long after putting on boxes. I would at least double the number for extracting.

P. H. ELWOOD.

a. Ten. But that's a very rare thing—seldom more than eight. b. Just before the harvest when the queen occupies the most room. This for comb honey. It is quite possible, however, that, all things considered, it is best to have the same number all the year round.

C. C. MILLER.

I have used as many as 48 in the best part of the season, when extracting. When boxing I would use 8, and the same for wintering. During the period when I am handling and preparing for the yield of either extracted or box honey, I use a number in proportion to the strength of the colony.

L. C. ROOT.

If I used the L. frame I would never allow a colony over seven when working for comb honey, and would use but five for a new swarm, up to the time of fall honey; then I would give them the seven,

For extracted honey I would allow ten L. frames all the while, unless the colony were very weak in the spring, and give room enough above to keep them from swarming. G. M. DOOLITTLE.

a. I frequently allow the equivalent of 25 L. frames at a time. b. I vary the number of combs according to the strength of the colony, but the same number of bees in a colony will occupy and use more combs during the honey-flow than at other times. This applies to extracted honey.

O. O. POPPLETON.

Seven is my usual number, with eight or ten as an occasional variation or experiment. I do not vary the number after sections are put on. When I winter on four frames, as I often do, I simply add one or two at a time, in the spring, until they have seven. For extracting I would put ten below and eight or nine above. E. E. HASTY.

I do not use the L. frame, so I do not know whether this question was intended for me or not. My frames are nearly the same in capacity as the L. frame. I use eight brood-frames at all times, except in building up light colonies in the spring by use of the division-board. I practice contraction sometimes during the honey-season, not by removing frames, but by an entirely different and I think a more natural and a better way.

H. R. BOARDMAN.

Your question is not precise. I suppose you mean to ask, "What is the largest number of L. frames you allow a colony at any time for brood?" etc. I allow a colony for the brood-chamber, all the L. frames they can fill with brood, no more. Ten frames filled with brood is my maximum. Whatever there is over is used for strengthening up weak colonies or forming nuclei. A variation from this rule is "neglect of duty" as far as I am concerned. CHAS. F. MUTH.

I always try to get as many frames as possible filled with brood before the opening of the honey season, and have had 12 frames reasonably well filled by June 20. Most of my hives for comb honey hold only eight frames; and if a colony can do more than fill that number it must help a weaker neighbor. For extracted honey I have always allowed ten frames. Sometimes I allow the queen free access to three or more stories of empty combs, which I have known to result in twenty frames of brood. JAMES A. GREEN.

In using the Langstroth frames in the brood-chamber I would never use more than eight, because we do not want the L. brood-chamber larger than that. We have found splendid results to flow from contracting that size of brood-chamber to five L. combs during that part of the season when the bees were storing surplus, and at the time the creation of more bees would not bring them into the surplus harvest as workers. The time to contract or expand a brood-chamber depends entirely upon the periods of your honey-flow. I disfavor young bees for wintering; also extremely full colonies for wintering. JAMES HEDDON.

QUESTION 113.—*If you practice contraction, at what time do you contract?*

This question is answered by 112.

MRS. L. HARRISON.

I have never practiced contraction.

GEO. GRIMM.

I rarely use it except on new swarms, as given in answer to No. 112. G. M. DOOLITTLE.

On putting on supers. I don't believe so much in contraction as some. C. C. MILLER.

I do, and like it. I contract with a new swarm, in time of honey harvest. A. J. COOK.

I contract to the number of combs needed in the spring, and give more as needed. I don't contract to secure surplus. DR. A. B. MASON.

When they are placed upon their summer stands in spring, or when they commence gathering pollen and begin brooding. L. C. ROOT.

Not until the season is well commenced, and a fair amount of stores secured for winter, and the bees are building new comb. H. R. BOARDMAN.

Contraction does not seem to me to be suited to the needs of my locality. For comb honey I keep contracted pretty close all the time. E. E. HASTY.

Here we don't practice it. We contract only when a colony is too weak; but this should not happen when one is up to the business.

P. L. VIALLO.

I suppose this question refers to the contraction of the brood-nest, which I have practiced but very little, except when preparing bees for winter quarters. O. O. POPPLETON.

I contract in the early spring by placing a duck cloth over the lower frames or brood-nest, to facilitate breeding, leaving a hole for bees to go above for honey. R. WILKIN.

I contract the brood-chamber in spring only, in order to breed up. Reason, I want large colonies at the beginning of the season, and during the season I don't want to be obliged to feed in the fall. CHAS. F. MUTH.

I don't practice contraction any further than to put the bees on to one tier of brood-combs, 8 combs. Do that when the bees are strong—that is, when there are bees enough to fill the brood-nest and a case of sections. E. FRANCE.

We are opposed to contraction. Mr. Metelli (see answer to 111) answers for us, "To have colonies for honey in good order for the next spring you have to give them large hives, and to prepare them during the previous summer." DADANT & SON.

See my answer to 112. You may rest assured that I practice contraction, and know by experience that it is one, if not the greatest improvement, in modern honey production, whether for comb or extracted honey, but especially for the former. JAMES HEDDON.

Always at the time of hiving a swarm; generally as soon as a colony has swarmed, often before a colony has swarmed at the beginning of a honey-flow. With regard to the last two, and especially the last method, I am not altogether certain as to the advisability of contraction. JAMES A. GREEN.

Sometimes when boxes are put on, but usually when the queen is removed or artificial swarms made if there are any such. We formerly reduced the number to five, when the queen was taken out, but have since preferred to leave in another. If contracted too much, the quality of box honey suffers, and I think there are more piece boxes at the

close of season. Our first contracting for comb honey was in the season of 1873 or 1874, and the swarms were brought down to four of our combs, $10\frac{1}{2} \times 16$ inside.

P. H. ELWOOD.

QUESTION 114.—*How many pounds additional surplus do you think is gained by contracting?*

I do not know.

O. O. POPPLETON.

I have never had any experience in that line.

E. FRANCE.

With my method, no additional surplus.

DR. A. B. MASON.

Not an ounce, but more honey will be brought to the surplus box.

DADANT & SON.

I could not give an estimate. I think the gain pays for the trouble, and more.

A. J. COOK.

If by this question contraction during the honey-flow is meant, not enough additional to pay for the trouble.

MRS. L. HARRISON.

In some localities I have no doubt but that there is some gain by contracting; but here our colonies are so strong at the time of the flow of honey that there is no gain.

P. L. VIALLO.

Possibly as many pounds as they would store in the additional combs, say 15 or 20; but taken for a series of years, I'm not so sure they would store any more, and in any case it necessitates feeding usually.

C. C. MILLER.

Many stocks that would be lost if the number of combs were not reduced, are saved by contracting, and are in condition for gathering surplus. In such cases the gain equals the difference between entire loss and what proper management will secure.

L. C. ROOT.

I do not practice the manipulation in question. As excessive swarming is the main difficulty with me, I think (if I do not know) that getting an extra-large colony, and then crowding them above, would only make them swarm directly with no gain in pounds of honey whatever.

E. E. HASTY.

I don't believe that any additional surplus can be gained by contracting the brood-chamber during the honey season, unless the bee-keeper's time is worth nothing. Honey or sugar has to be fed again if a dearth or a cold wet spell follows the season, and honey or sugar has to be fed again for winter stores.

CHAS. F. MUTH.

I do not know, because I never weighed carefully to get at the exact number of pounds; but I get more surplus and less honey uselessly consumed by the bees; get that surplus in better and more attractive condition, and handle my colonies more easily and safely during the fall, winter, and spring, by practicing contraction.

JAMES HEDDON.

I have not practiced contraction long enough through good and bad seasons to answer definitely. I can recall instances where it seemed to me that contraction secured 25 pounds of honey more than would have been had without it. Doubtless this is more than could be expected on an average, but I feel very sure that contraction pays well when properly managed.

JAMES A. GREEN.

Contraction is now having a run. It is carried to extremes, and its benefits overestimated. With the inexperienced, and with honey-boards, particularly the queen-excluding board, it may make quite a

difference. In any case a part of the early honey that is usually stored in the brood-combs will be stored as surplus. This is the honey that bees usually winter best on.

P. H. ELWOOD.

Not any more, if you leave the colony as much as it ought to have. It may be different in other locations, but with me I find it safest to leave a colony all the white honey it has stored over and around the brood in an eight-frame Langstroth hive. Of course, if I should crowd them they would have to store part of this as surplus; but I do not find it safe policy here, as I have no fall honey to fill up on.

GEO. GRIMM.

In some seasons probably nothing is gained by any system of contracting the brood-chamber. The amount additional gained depends upon the season, strength of the colony, manner, and extent of contracting, etc. When honey is coming in steadily it can all or nearly all be forced into the surplus chamber for a period of about 20 days; but we must not lose sight of a most valuable fact, that hives or fixtures, or methods, however perfect, *will not produce honey*.

H. R. BOARDMAN.

Not any, if you call winter stores a surplus. Bees will store all the honey they can gather if they have sufficient room, no matter whether that room is in a nail-keg, barrel, old box hive, or one of the latest improved hives. All we accomplish by contraction is to get the most of the surplus, or the most of all of the honey gathered by the bees, stored in our neat sections, instead of in the body of the hive. If I have ever made it appear that bees would gather more honey according to their numbers where contraction was used, I wish to ask pardon, and correct the mistake. By contracting at the right time, or allowing contraction of the brood to be done by swarming, we save the amount of honey that an extra amount of brood would use, to go into our surplus. As this brood, when hatched into bees, would become consumers, this item is worth looking after.

G. M. DOOLITTLE.

Well, friends, I have been for a good many years rather of the opinion that contraction did not amount to very much, any way. Of course, colonies do well where the brood-nest has been contracted according to the latest and most approved theory; but I am afraid we lose sight of the fact that they also do well where no contraction is practiced. To make it a little plainer, I have seen a colony of bees build up, raise brood, and prosper at a tremendous rate, when they were in two-story Langstroth hives, with 10 frames below and 10 above. When more room was wanted they took it at the side or overhead, just as they chose. They did not have any dysentery nor spring dwindling, nor any thing of the sort; and I have seen this happen when colonies that were fussed up and fixed up did not do nearly as well. At the same time, I have known a tolerably fair colony that was raising brood at a very good rate, apparently killed by removing the quilt over them to put on a feeder. The openings made by turning up the quilt so as to give the feeder a place, permitted the warm air of the brood-nest to escape. They were found dead after a severe cold spell in the fore part of April. Other colonies that did not have the quilt over

them disturbed, stood the cold snap without any apparent injury. I am rather inclined to think that there are extremes both ways; but I believe a good nice dry worker comb is about as good protection as any sort of division-board. Perhaps you begin to think that I do not have any very decided ideas in regard to contraction, and I do not know but that you are about right.

HOW TO MAKE OUT AN ORDER FOR GARDEN SEEDS, ETC.

ALSO SOMETHING ABOUT DOING BUSINESS IN SUCH A WAY THAT IT WILL ADVERTISE ITSELF.

EVERY season it makes me feel sad to see the amount of paper and the amount of work that not only our customers but our clerks here in the office often use to make an order, or make out a bill for a few cents' worth of garden seeds. Now, please have a little faith in Uncle Amos, and let him convince you that he knows best. First suppose you want 9 papers of garden seeds. Almost all of you would commence:

One paper of Select Very Early Jersey Wakefield cabbage seed 5 cts.

The next item would be in the same way, and so on for the whole nine. Some of the friends who are in a hurry, sometimes, instead of "one paper," *nine times*, use ditto marks. When you get to the 9th figure 5, one above the other, I suppose that many of you go to work and "add up" the 5's.

Now, friends, you are wasting paper and time fearfully; yes, and you are wasting *money* besides, because many of you forget that 10 packages of seed are furnished at 4 cents each, so our clerks will probably charge you *more* for 9 packages than they would for 10. Now, then, let me tell how I would do. Thus:

Please mail me garden seeds as follows: One paper each—Wakefield cabbage, Eclipse beet, Forcing carrot, Snowball cauliflower, Self-blanching celery, Pepper-grass, Grand Rapids lettuce, Banana melon, Silver King onion, Alaska peas, 10 papers at 4 cts., 40 cts.

You will notice in the above, that, instead of giving the long name of the article as given in the seed catalogues, I have given only just enough so there can be no mistake. "Wakefield cabbage" tells what you want just exactly as well as if you wrote out "Select Very Early Jersey Wakefield cabbage."

Now, where you order simply five-cent packages the matter is very easy, you see; but suppose you have discovered that it is a great deal cheaper to buy seeds by the ounce than to get it in five-cent packages—how then shall we do? The objections to saying "one ounce each of the following seeds" would be, that they are not all the same price. An ounce of one may be 10 cts., and another may be only 5 cts., and still another may be 25 cts., and so on. Well, this makes the matter a little more complicated, but it can be arranged so as to economize space almost as well as the other packages. I learned it in the jewelry business. The traveling runners whose bread and butter depended on speed and expedition would make a correct invoice of 100 or more items on a small piece

of paper, and they would do it in a very few minutes in the way I am going to show you. Now then: Suppose you are buying ounces as follows. Start your letter this way:

Mail me one ounce each of the following seeds:

Eclipse beet,	⁵	Winningsstadt cabbage,	¹⁰	\$ 15
Self-blanching celery,	⁵⁰	Rawson's cucumber,	²⁵	75
Grand Rapids lettuce,	³⁵	Danvers onion,	¹⁵	50
Parsley,	⁵	Early Globe radish,	⁵	¹⁰
Lady-finger radish,				20
Mikado tomato,	²⁵			25
				\$1.85

Of course, half-pints, pints, and quarts and pecks, can be run together in the same way; also quarter-pounds and pounds. If you want to make your order neatly, I would take a catalogue and go through with a pencil, marking the amount you propose to order, on the margin, all the way from asparagus to turnip. When you have decided on every thing you want from a certain catalogue, then collect the 5c papers first. If there are only 9, you had better make it one more so as to get the 10 rate. After you have collected the papers, then collect the ounces. These two items alone will save a deal of time and paper; and instead of a long lot of additions, you will have simply a matter of multiplication. Do you ask how it is when you want *two ounces* or *three ounces*? Well, for two ounces you can make a separate item. For instance, "2 ounces Palmetto asparagus, at 10 cts. per ounce, 20 cts.;" but when it comes to 3 ounces, by all means order $\frac{1}{2}$ of a pound. If you will just look at it you will notice that in most seed catalogues 3 oz. will cost you as much, and oftentimes *more*, than $\frac{1}{2}$ pound. In fact, I am pained a great many times to see our clerks charge a customer more for 3 ounces of seeds than they would if the order had read $\frac{1}{2}$ pound. When I remonstrate, they reply, "Why, he wanted only 3 ounces of seeds, and he sent the exact price according to the catalogue." Now, I do not like that sort of logic at all. I never saw anybody yet who would complain because you sent him *more* seeds than he asked for; and when a man sends money enough to pay for $\frac{1}{2}$ pound of parsnip seed, he should have $\frac{1}{2}$ pound, even if his order does read 2 ounces. You will notice by the catalogue that parsnip seed is 5 cts. an ounce, or 40 cts. a pound; and you will notice, also, on the first page, that we sell $\frac{1}{2}$ lb. or $\frac{1}{2}$ peck at peck rates; 2 ounces cost 10 cts.; $\frac{1}{2}$ lb. costs 10 cts. Some of the friends still urge, that, when you give a man *just what he asks for*, that that is enough. My friends, if you want to build up a business, or if you want to glorify the Master, make it your business to give your patrons *more* than they ask for whenever such a chance offers. Why, it is just fun for me to give a man $\frac{1}{2}$ pound of seed when he sent for and expected only 2 ounces; and I should not wonder a bit if our present large business has been built up a good deal in just that way. The great world at large has had ample experience in sending away their money and getting *less* than the printed advertisements promised,

or getting less than they expected. But there is a great open field—a big unexplored region—for business and happiness and peace of mind in giving not only *all* you agree to give, but “good measure, pressed down.”

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from \$1.00 to \$1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows: viz.: Sheer Off, Silver Keys, The Giant-Killer; or, The Roby Family, Rescued from Egypt, Pilgrim's Progress, and Ten Nights in a Bar-Room. We have also Our Homes, Part I, and Our Homes, Part II. Besides the above books, you may have a photograph of our old house apiary, and a photograph of our own apiary, both taken a great many years ago. In the former is a picture of Novice, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

THE CALF AND THE BEES, IN TWO ACTS.

We have 13 hives. My teacher is cross. She lives near us. We have a little calf; and next summer,

when we let her out, she will go by the hives and tip one over, and they will sting her nearly to death.

I have sent you these pictures. I drew them myself.

LOUIE MICHAEL, age 12.

East Buffalo, N. Y., Feb. 7, 1889.

Your drawings, friend Louie, are very good. We reduced them, and made them almost fac-similes of yours. What is a fac-simile? Well, that means a “make-like,” or something just like the original.

BEES HAVE ALWAYS PAID WELL.

My father had 48 stands of bees, but he has sold them all but 4. We left these to our renter, on shares. When we put them in the cellar they were heavier than ever before. We have rented our

farm, and we are packing up to move; but we mean always to keep bees wherever we go, for they have paid us well. We have taken GLEANINGS for so long I can't remember when we didn't take it. We like it very well, and we are going to keep on taking it, for we should miss it very much.

Traer, Iowa, Feb. 21, 1889. J. L. PROVIN, age 14.

A CRIPPLED BOY WHO HELPS PAPA.

I am a little crippled boy, 12 years of age. My pa has 63 stands of bees. I help him tend them.

Newbern, Ia. DAVID C. MALONE.

BROTHERS' BEES.

My two brothers keep bees, and have 11 hives. They keep them in the cellar. They carried them in their arms. My grandfather says that the bees in the cellar ought to be kept at 42 degrees in the winter. In warm days they make a great noise. We had six in the spring. The wheat crop was poor last year.

ROBERT DAWSON.

East Dayton, Mich.

PAPA'S WINTERING-CELLAR.

□ Papa winters his bees in the cellar. He commenced last spring with 10 swarms, increased to 24, and got 600 lbs. of extracted honey and 100 lbs. of comb honey in 1-lb. sections. Three hundred and fifty pounds was from mammoth clover, and the rest was from buckwheat. The cellar that papa keeps his bees in is a place dug out under the house, about 3½ feet deep, not plastered. Nothing was done to it but to bank up the house well. But he winters successfully in it.

BERTHA BOARDMAN, age 9.

Weston, O., Feb. 22, 1889.

HAULING BEES TWELVE MILES IN A TWO-HORSE WAGON.

My pa has 14 hives of bees, and I have one. The 14th of last May the levee broke, and on the night of the 14th pa hauled our bees 12 miles without breaking any comb. The 11th of August he brought them and 15 of grandpa's back to the bottom, without breaking or damaging the comb. To prepare them for hauling he nailed cleats over the entrances, then he set them in the wagon and packed clover hay all around them tight. We did not have a very big honey-flow last year. We got about 360 lbs. for home use. They have from 60 to 70 lbs. to the colony now. We are wintering on summer stands. They are all right so far. We use A. I. Root's Simplicity hives. I am an A B C scholar, and read GLEANINGS.

ABBIE HOSKIN, age 14.

Louisiana, Mo., Feb. 19, 1889.

HOW PAPA FEEDS BEES.

I am a little boy seven years old. I was paralyzed three years ago, and have never gotten over it entirely. I have a pony and a little saddle. I can go to town and get the mail, or any little thing that papa or mamma wants. We live a mile from town. My papa feeds bees two ways. One way he takes a little square piece of board and cuts small grooves in it, two of them crosswise, from corner to corner, one from top to bottom, and one from side to side. Then he takes a goblet, with the bottom broken off; fills it with sugar syrup; puts the board on it, and turns it bottom upward and sets it in the hive. The bees take up the syrup as it runs out in those grooves. But he likes the other way best. It is

this: Take out the empty combs; pour syrup over them; hang them back in the hive. Papa has 42 colonies. He has extracted once, and they are full again. He sells honey at 15 cents a pound, home market. We got some strong honey, described by S. G. Christol, page 851, from the white-top milk weed. I think the strong or hot part soon evaporates. CLAY DILLERAY.

Milford, Tex.

The grooved-board feeder is illustrated and described under "Water," in the A B C of Bee Culture.

THROWING MUD, AND SHOOTING, TO BRING DOWN A SWARM.

Last summer papa got 100 pounds of honey from 12 colonies, and my brother-in-law got 60 pounds from only 2 colonies. Papa caught two swarms when he was extracting. He heard a lot of bees buzzing, and he looked up and saw a swarm. We threw mud at it, but it would not come down, and then papa sent me home after the gun. He fired both barrels at it, and I kept throwing mud, and at last it settled on a pile of brush in a ditch. Papa put a hive there, and at evening they went in it. My brother came down, and he, papa, and I went down to the hive and carried it to the apiary. We caught the other the same way.

DANIEL W. HIGGINS, JR.

South River, Md., Feb. 22, 1889.

Well, well! was it the mud-slinging or the shooting that finally induced the swarm to alight, or did the swarm settle when it got a good ready, regardless of either the mud or the shot? We suspect they got a good ready.

EXTRACTED SELLING HIGHER THAN COMB HONEY; HOW PA FASTENS FOUNDATION INTO WIRED FRAMES.

My pa takes GLEANINGS, and we are glad when it comes. I have a little brother, six years old. We go to school every day. My pa has 85 stands of bees, packed in clover chaff, outdoors. Pa says that he is going to extract more honey next summer than he did, as it sells better than comb honey. I help pa extract honey. I have been stung only two or three times in my life. Charley is afraid of the bees.

Pa fastens the brood foundation in the brood-frames with the heat of a common lamp. He sets the lamp on the table and lays foundation in the brood-frames and holds the frame over the lamp with his left hand so as to heat the tin wire and the foundation. Then he passes the finger of his right hand over the wire on top of the foundation so as to sink the wire into the foundation; and when it is finished it looks as if the wire were sewed through the foundation. We can fasten the foundation in cold weather as well as in warm. We did not get much honey last year, as it was too dry.

DORA KUNZ, age 8.

Linkville, Ind., Feb. 23, 1889.

You probably do nice work in putting in the foundation; but how your papa can heat the wire so that it will sink into the wax, without spoiling the foundation by too much heat, we do not quite understand. Is the foundation itself left as perfect after putting into the frame as before? Please tell us more about it in your next letter.

MYSELF AND MY NEIGHBORS.

CONTINUED FROM ISSUE OF MAR. 1.

Cast me not away from thy presence; and take not thy Holy Spirit from me.—PSALM 51: 11.

DURING the sermon that followed the Sunday-school, this peace and joy I have told you of still poured into my soul. The closing thought of the sermon was something like this:

Some people seem to imagine that it is not in their power to turn to Christ, any more than it would be in the power of an individual who is lost in Mammoth Cave to find his way out. If no guide were near to direct his steps, his case would indeed be hopeless; but Christ Jesus stands ever ready to lead every willing soul from darkness to light. In fact, he has said, "I am the light of the world. He that followeth me shall not walk in darkness, but shall have the light of life."

Dear friends, I had unconsciously, as it were, reached the top of one mountain. I want to use here one verse and chorus of a familiar little hymn that expressed my state of mind at the close of that sermon:

The Savior comes and walks with me,
And sweet communion here have we;
He gently leads me by his hand,
For this is heaven's border land.

O Beulah land, sweet Beulah land,
As on the highest mount I stand,
I look away across the sea
Where mansions are prepared for me,
And view the shining glory shore,
My heav'n, my home for ever more.

Last Sabbath evening I listened to a minister who made the broad declaration that all humanity are seeking happiness. I thought at the time that his statement was open to a little question; but perhaps he was pretty nearly right. Well, if this is true, dear friends, suppose we consider for a moment human happiness. Many of you besides myself have discovered that it comes oftenest when we are not seeking it. It was a good deal against my inclination that I had decided to wait until the Sabbath was passed before resuming my travels. My reward had come unexpectedly. Perhaps part of it came because I refused to go with the boys who wanted to show me the natural attractions of the little town, but stayed inside of my room, and studied God's holy word all through the bright sunshiny morning. Jesus tells us, in that beautiful parable, that those who had been all their lives busy ministering to him were not aware of it at all. When he called them to their reward they replied, "Lord, when saw we thee a hungered or thirsty, and gave thee drink?" etc. Instead of *boasting* of what they had done, they had not thought it worth mentioning. A great blessing had come to me, simply because I was doing my duty, without any thought of reward. But I had been vouchsafed a taste of the waters of life that I presume I shall never forget.

Whosoever drinketh of the water that I shall give him shall never thirst; but the water that I shall give him shall be in him a well of water springing up into everlasting life.—JOHN 4: 14.

And I here wish to leave my testimony, to

the effect that there is no enjoyment nor happiness in this world to be compared with it. Such seasons as these, however, are usually of brief duration; and while we are yet human, perhaps it will always be so. There is quite a temptation to skip the remainder of the events of that Sabbath day; but perhaps it might be profitable to consider how I came down from the mountain, as well as to relate how I unconsciously got up.

As the service closed, I felt sorry to know there were no more meetings till evening. At dinner I compared notes with the boys who had been seeking pleasure in the ways I have already mentioned. What should be done during the afternoon? I read awhile; and then feeling the need of exercise (or at least I thought I did) I decided to walk out a little by myself. The suggestion came into my mind, that I not only needed some of the

mountain air, for which the place is widely celebrated, but that, if I could find one of those springs at some quiet place there would be no harm to take a drink of the famed medicinal waters. Of course, I could wait until the morrow; but if I expected to get any marked benefit from the celebrated waters, it behooved me to get a drink as soon as possible, that I might be able to take many drinks before I was called upon to leave. Even in my boyhood I had always a great fondness for ginger pop, and mineral waters that owed their pungency to imprisoned carbonic acid. The pop of the cork and the foaming in the glass always had a certain fascination, and I must confess that the taste of these foaming drinks has always been more or less agreeable. I had been told that the water of Manitou Springs had a fashion of foaming and sparkling as it comes out of the ground—a foaming, sparkling draught from nature's own laboratory. I did not know exactly where the springs were located, but I thought there could be no harm in walking out along the railroad, all by myself, and so I started. The walk was very pleasant indeed—or, rather, it would have been pleasant had it been some other day than Sunday, for my conscience was making me feel a little uneasy. When perhaps a quarter of a mile from my boarding-place the

track ran into a tunnel. Conscience said it was time to go back; but curiosity pointed to the strange rocks which had been cut and chiseled in making an opening. After I got in a little piece I saw daylight from the other side, and I thought I would just look through. When I did so, I saw another tunnel, more wonderful still. Of course, I went through the last tunnel, and, sure enough, right before me was one of those wonderful effervescing springs. Some benevolent (?) individual had built a pretty little summer-house over it.

Below is a picture of the spring as it met my view. In the distance is the white summit of Pike's Peak, where I had seen the snow blowing in the morning. The picture, however, is not from a photograph, and does not at all do justice to the mountains.

The summer-house built over the spring is very lifelike.

Some steps ran down to the sparkling spring, and a tin cup hung invitingly by a chain. Just then I noticed that

not only young men but women

also were passing to and

fro, evidently out that

Sunday afternoon seeking

happiness and recreation,

or some sort of excitement.

I thought I would take

just one drink, and then go

back quickly to my lodging-

place. When almost to the

brink of the spring I discovered

in a room, close by, a gathering

of ungodly people; and from the looks of the

bottles and decanters, I judged the place was for the

traffic in intoxicating liquors. Should I turn back, or go ahead and

taste the waters? Since I had got so far, I decided to take just a taste; but I began to feel very bad and uncomfortable. It seemed as if they were all looking at me, and saying, "There is that man out here this Sunday afternoon, who talked so well in the Sabbath-school. After all his talk, he has as much curiosity to see things, and just as much of a desire for a little excitement and stir, even if it is Sunday, as the rest of us."

I tasted the water, and dropped the cup hurriedly. Somebody has said, that "stolen waters are sweet." My young friends, don't you believe it. It has never been true in my experience. I noticed the sparkle of the gas as it came bubbling up from the water from the bottom of the spring,

THE UTE SPRING, MANITOU, COLORADO.

and the taste had a decided snap, like pungent soda; but I did not care very much for it then. I decided it was not worth the cost on that Sabbath afternoon. I didn't think at the time (but I did afterward) of the text, "Whosoever drinketh of the water that I shall give him, shall never thirst." Well, what was to hinder my retracing my steps as quickly as I could? Nothing; only, as I started to go back, something suggested (very likely it was Satan) that, if I climbed that big hill to regain the railroad track, I should be all in a sweat, and one ought not to look sweaty with exercise on Sunday. Before me was a smooth traveled road that led back to my hotel, without the necessity of climbing the hill to reach the track. It is true, this traveled road led through the business part of town; but I did not think so much about that just then. As I passed along the road I saw more and more people, who, it seemed, eyed me as did the others. Most of them were shabbily dressed. Some were smoking and swearing, and I had a sort of feeling that my presence on that street was something of an indirect encouragement to them to think it was right and proper to be seen on the streets on the Sabbath day. Pretty soon a path turned off into a quiet little grove, or ravine, beside the brook. This path, so far as I could see, went along almost parallel with the public road. "There," thought I, "I can take this path and thereby escape the crowd and their questioning gaze, and it will no doubt lead me just as directly, and may be *more so*, to my hotel." Do you remember how Christian, in Pilgrim's Progress, started off a little from the straight and narrow path, and, without actually knowing it, got further away? Well, it was so in my case. The path led down by some more springs, and, for some reason or other, I thought I would just taste the water of these springs—it wouldn't take more than a moment—and I wanted to see if it were all alike. Was it really so, that these were not as good as the first ones, or was it my guilty conscience that made it seem so? I met more untidy people, and pretty soon I found a wire fence intercepting my path. The owner of the ground, evidently not liking so many tramping over his lands, had *recently* made the fence. As soon as I saw it some thing said:

"Now, old fellow, you will be sure to tear your nice clothes before you get over that wire fence. You know you always have some mishap when you go off so on Sunday; and you may *depend on it*, you won't escape this time." I thought of the morning, and I felt feverish and nervous. Several times I had tried to walk slowly and sedately; but before I knew it I was rushing ahead again very much as A. I. Root does on week days. I would have turned back and retraced the path until I came to the highway again, but I was getting nervously impatient. How I did long for the protecting walls of the Mountain View House, or even to be so near its doors that no one would think I was guilty of strolling about on the Sabbath. I decided, that by being real careful, I could get over that wire fence, and not have my

clothes torn. I pressed down the top wire, carefully gathered up the coat-tails of my Sunday overcoat, and succeeded in stepping over the fence without a rag of my clothing touching a single barb. Then I decided to walk slowly and sedately the rest of the way, and that nothing should entice me to wander about any more during the afternoon. After I had gone a few rods I happened to look down at my polished boots. They were newly blacked, expressly for church and Sunday-school. Something caught my eye that troubled me at once. I reassured myself, however, by saying mentally it was only a *wide blade of grass* that had fallen across my boot. Nervously I undertook to brush off that "blade of grass." As I found it would not brush off, the sweat began to start on my forehead. One of my nice new boots (a pair that just cost \$7.00) was actually cut from ankle to toe, and was gapping open wide, showing my blue stocking underneath. I have heard that pickpockets sometimes carry a lance so sharp that it will cut open a pocket, without the owner being aware of it. Had a pickpocket suspected I carried money in my boot, I should have thought it *was* his work. How was it possible that that great cut was made without my knowing it? Oh, yes! When I lifted my last foot over that wire fence, I do remember a peculiar singing "zee-e-e-p," and that sound was made by one of those keen barbs as it cut my boot. I was near to the pastor's house. Perhaps they were watching me out of the window. May be some of them would come out to the door just as I came by, and find me sweaty, dusty, flushed, and uncomfortable, with a great gash across my foot. Satan whispered to turn around and go and get a shoemaker to sew it up before church time. Just then, however, I thought I could see where glimpses of Satan's cloven foot had been visible all the afternoon, and I said, very decidedly, "Get thee behind me, Satan." The minister's folks *did not* come out, and I was enabled to get safely to my tidy little room in the hotel; and when there I knelt by my bed and asked the kind Savior to forgive me for my folly of the afternoon. And that is the way, dear friends, I slipped away down in the "Valley of Humiliation" from that high pinnacle where it had been my pleasure to stand but a few hours before.

I had been asked by the pastor to take part in the young people's Endeavor Society at half-past six, before preaching services, and I was on hand, I believe, before anybody else. We have often been enjoined to "put our best foot forward." So far as that was concerned, however, I was trying to keep my best foot in the background, you may be sure. When the proper time came I gave in my testimony. But I was somewhat like a crippled soldier. The spirit that was with me in the forenoon was not gone, but it was a good deal dimmed. However, I went to bed feeling happy that the Sabbath day as a whole had not been so very badly spent.

I found that my train did not leave till 2:35 in the afternoon, on Monday, so you may be sure I was up bright and early, ready

to make the best of my time before leaving. On questioning in regard to the liveries, and what I could get a rig for, the landlord suggested, that, if I were used to walking, I might make the whole trip on foot, and thus save quite a little money. The two caves and the Rainbow Falls he thought I could make by noon, taking in the springs on the way, and the Garden of the Gods might be visited before the train left if I were not too tired. Can you imagine with what a light heart I started forth after my early breakfast?

The accompanying picture gives you another glimpse of Manitou. The building in

A GLIMPSE OF MANITOU.

the foreground is one of the fine large hotels. A pretty fountain plays in front of the piazza, on the lawn. A rustic bridge across the stream that comes from Rainbow Falls, and the caves I am about to describe to you, are in the mountain off to the right. Pike's Peak looms up in the background; in fact, Pike's Peak seems to be always before you, and every glimpse seemed to say to me that it could not be very far away.

I was down through the little village, and had a drink from the springs, almost before anybody else was stirring. The waters were much pleasanter than they

were the day before, but I was not very thirsty just then. Then off I went, as happy as a schoolboy when school is out, up the mountain side, for the Cave of the Winds. The road very soon began twisting amid the rocky cliffs, one way and then another, until one could hardly see many rods ahead. Then the cliffs towered away up toward the sky, in some cases leaning clear over the road, until it seemed as if we were in a land of giants. It was up-hill work; but what cared I, with the love of God in my heart? It seemed that morning just a *pleasure to climb*; and before the sun was fairly up I had made the two miles up the mountain-side, and

stood at the foot of the cliff whereon was found the Cave of the Winds. Now, it is a little funny, but this cave was discovered only three or four years ago by a band of Sunday-school boys. To keep them busy, and perhaps out of mischief, the Congregational pastor had organized what he called an exploring band; and the boys composing this band, when they had the leisure, devoted their time to exploring the mountains about Manitou. As I stood and gazed upward I saw in the side of a steep cliff, perhaps 500 feet above me, a fissure in the rocks. This fissure was a sort of crack where the mountain had split in two, as it were, leaving a space of perhaps a yard wide. Now, the rock was rough enough so the boys by reaching from one side to the other had climbed up in this fissure for a hundred feet or more; and away back, out of the sight of human eyes, either from below or above, they found the cave. I did not rest long before I commenced climbing the steps. Then a sort of sheep-path led up along quite a distance further. Then some rude stairs took me to the foot of the fissure. Wooden timbers were put across the fissure, and stairways took us up to the opening. See cut on next page. I knew before I started out, however, that the Cave of the Winds was closed at this season of the year; so after resting a while, and

trying to imagine how the boys felt when they reached this spot, by means of other ladders I ascended clear to the top of the opening, and stood nearly on the summit of the mountain. A good many people get dizzy when up here, and I sat down and meditated a while before I took what seemed to be really a perilous passage on the very edge of the cliffs. Still another narrow path wound up and up, until I reached the very summit of the mountain. The sun was just rising, and a refreshing breeze seemed very grateful after so much climbing. By my side was a little pyramid of stones. This

pyramid was the work of tourists, each one contributing a stone to it. Although I was panting for breath, I selected one also, and placed it near the top. A good many had left business cards, and some had scratched their names and addresses on the stones. I looked off toward the village, and there in plain sight was my hotel, Mountain View; but, oh how small and insignificant it looked! The landlord had, before I started, pointed out to me the Cave of the Winds; but as I looked from the hotel, all I could see was a few rough rocks that seemed not larger than a common-sized house. But

other cavern. Before I could get in, however, I had to go still further down the mountain to where the guide lived. He informed me they did not open till eight o'clock, and, sure enough, it was only *just* eight. The points the landlord said I could make by *noon*, I had already made, except going through the cave. Come to compare notes, the guide had been an Ohio boy, and, still further, he was brought up in the neighboring town of Akron. We were old friends in short meter. While he was lighting his lamps, and getting ready to go into the cave, I sat down on the steps, thinking I

had better economize my strength, although I didn't feel tired a bit. My eye glanced across between a couple of mountains, and there was Pike's Peak again, with the snow rolling and blowing.

"Mr. Snyder, they tell me it is *thirteen miles* to the top of that mountain over there. Why, it seems as if I could skip to the top of it in a little more than half an hour."

"Well, I think I can teach you a lesson if you care to look through our big telescope. It cost us about \$250, and therefore we are obliged to charge ten cents for the privilege of looking."

"Cheap enough, my friend. I want to see every thing you have that is worth seeing, and here is a five-dollar bill to cover expenses. While you are making your change I will look at Pike's Peak."

The instrument was very soon adjusted by his practiced hands; but before I put my eye to the glass he spoke:

"Mr. Root, I want you to tell me first if you can see any thing like a house on top of Pike's Peak, with the naked eye."

"Why, I think I could see a house if there were one, but there is surely nothing of the sort. It is just a scene of snow and blank desolation."

As I replied, however, I put my eye to the glass, and, lo and behold! There was quite a good-sized stone house on the peak—some outbuildings around it, a flag floating from the highest part of the house, and smoke

coming out of the chimney, while the blowing snow made one fairly shiver as he looked through the glass. Of course, I uttered an exclamation of surprise, and then took another look with my naked eye. After the telescope had shown me what there was to be seen, I readily fixed my eye on a mere speck that I decided must be the house. And all at once the old mountain shoved back fully ten miles. You see, when my eye had learned to pick on something with *known dimensions*, things then assumed their proper size and distance,

ENTRANCE TO THE CAVE OF THE WINDS.

when I came to stand by them, they loomed up nearly a quarter of a mile high. Now, this is one reason why we can not comprehend the height of a mountain. There are no familiar objects with which to compare things, and our eyes deceive us. More of this anon.

After being satisfied with my view I started on the downward path, to take in the Manitou Grand Cavern. Going down hill is comparatively easy work. (Did you ever know it, boys?) It was not very long before I stood before the locked door of the

RECENT DEVELOPMENTS

CONDUCTED BY ERNEST R. ROOT.

THE DOVETAILED HIVE, AGAIN.

THE new hive seems to be taking well, especially the dovetailed feature of it. The only serious criticism that has been offered is the dispensing of the bee-space *above* the brood-frames, in the hive, and, instead, putting it below. As many good friends, prominently among the number Mr. Heddon, thought we were making a mistake, we called a council comprising, as usual, A. I. R., the foreman, Mr. Calvert, and your humble servant. After discussing the matter in all its bearings, we saw our way, without any additional expense, to put the bee-space *above* the frames, and, of course, make the honey-board bee-spaced on one side only. To provide for a bee-space below the frames, we make what might be called a sunk or bee-spaced bottom-board, one side open for an entrance. This bottom-board is simply a cover, as shown in the engraving on page 189, with the projecting shoulder of one of the end cleats cut down so as to be made level with the board itself for an entrance. A $\frac{3}{4}$ -inch strip is nailed on to close up the two sides. As a result of this change, the cover-board and bottom-board are exactly alike, except that they are cleated a little differently, and the bottom-board can be used as a cover, although the cover can not be used to answer the purpose of a bottom.

Fortunately it was not too late to change the bee-space from the bottom of the frames to the top. All who have sent for the Dovetailed hive will receive them with the bee-space above the frames, and the bottom-boards bee-spaced as before explained. Perhaps it may seem a little strange that we should think of abolishing the bee-space in the first place. We had not then discovered a feasible plan whereby the space could be put above the frames, without an additional expense. In constructing this hive, the one feature of economy has been kept constantly in view, and we believe we have succeeded, as many letters at hand testify.

HIVE-LIFTERS, AND CARRYING HIVES.

Some time ago I stated that we would give something more on the matter of carrying hives. In compliance with our request in GLEANINGS, quite a number sent in descriptions of the devices which they were using for carrying hives; but scarcely any of them seemed practicable for carrying the *Simplicities* or any other than some particular hive. They either cost too much or else were complicated. Mr. J. H. Griffith, of Kingsville, Ontario, Can., and G. L. Jones, * of Grand Ridge, Ill., suggested a method of lifting hives, which I have modified somewhat. The engravings above explain the whole thing. It is simply a wire bail bent in the form shown in the engraving at the right, with hooks formed at the ends of the wires. For convenience in handling, a neat

bail handle is formed into the bend. It is very simple, and quickly made, and a pair of them can be made at a cost not to exceed 25 cents. You will notice that they will pick up not only the *Simplicity* hive itself, but the bottom-board also. The operation of attachment is very simple; push

WIRE BAIL FOR CARRYING HIVES.

the hooks into the soil, close to one side of the bottom, catch the beveled edge of the rim of the bottom-board, and the wire bail is caught. The other bail is attached in a similar manner. The apiarist can, either with or without an assistant, now lift up the hive. If the colony is a heavy one, and there are many to be moved, it would be advisable, of course, to employ an assistant, as shown in the right in the engraving above. If, on the contrary, the hive is not a very heavy one, he can, without very much difficulty, handle it as shown at the left. Perhaps it may be urged that it is almost as handy to put the fingers under the bottom-board; but if you consider a moment, you will see that it is not a very easy task to lift a burden when the body is stooped clear over in an awkward position. One can handle a much greater weight in an upright or nearly upright position, as shown in either of the figures above, than he can when the body is inclined horizontally. But the bail is a greater convenience when there are two to carry the hives, because then the palms of the hands are not twisted out of their natural position. The two figures were taken from a photograph.

To test these hive-carriers, Mr. Spafford and I attached them successively to several chaff hives, which, you are aware, are considerably heavier than the ordinary *Simplicity*. We found we could lift them with ease, and carry them to any place desired.

As they can be used on any hive with tight or loose bottom-board, I think they may prove a great help. The time is now approaching when it will be necessary to carry the bees out of the cellar; and to accommodate those who do not care to make them, we will furnish them for 25 cents per pair, or 10 cents extra when sent by mail.

P. S.—Since writing the above I discover, quite by accident, that one Wm. K. Deisher, of Kutztown, Pa., illustrated and described something very similar in GLEANINGS for 1883, page 607. Mr. D.'s implement was made of $\frac{3}{4}$ -inch iron, rather heavier than necessary. That described above is made of ordinary bail wire, such as is used for pails. Mr. K. says it is very handy, and that two boys can carry even a chaff hive about with ease.

* Mr. Jones, in a letter, says he carried into the cellar over 100 hives with such a device.

GLEANINGS IN BEE CULTURE.

MEDINA, MAR. 15, 1889.

Wherefore do ye spend money for that which is not bread,
and your labor for that which satisfieth not? ISA. 55:2.

THE "SCIENTIFIC LEGERDEMAIN" STORY AGAIN.

The "scientific legerdemain" story, see page 81, now comes to us in the columns of the *Register*, Troy, Pa., and they copy it from a paper called the *Washington Star*. Will those of our readers who are acquainted with either of the papers please call their attention to our article alluded to above?

DIMENSIONS OF LANGSTROTH FRAMES—SEE P. 69.

Friend Alley asks why I should send to Mr. Langstroth for dimensions of frame to the L. hive, when I already had the dimensions in Langstroth's book. It was not only the *dimensions* I asked for; but I asked friend Langstroth, while he was visiting Samuel Wagner, something like 25 years ago, to send me a sample frame by express, just as he would have the frame. I wanted to know the dimensions of the different pieces, the way in which they were put together, the kind of nails to be used, and all about it; and I wanted one made according to his latest ideas in regard to the matter, for the frame at that time had been already a good many years before the public.

THE FRUIT-PRESS AND VEGETABLE-STRAINER AS A HONEY-EXTRACTOR.

OH dear me! I entirely forgot, in my description on page 130, to mention that the above machine would answer for pressing honey out of the comb. In transferring from old box hives, if you have bits of comb containing honey just squeeze the honey out with the press, then put the wax in a bag by itself, to be squeezed after boiling. We are indebted to our good friend Thomas B. Blow, of England, for the suggestion. In fact, he calls it, in his price list, the "*honey-squeezer*," and he says it is a most useful article for the purpose. By the way, friend Blow sends out a very complete and comprehensive catalogue, 65 pages, of bee-keepers' supplies.

GLEANINGS MATTER, AND SOMETHING FOR THOSE WHOSE ARTICLES HAVEN'T BEEN PRINTED.

BEFORE us is a great heap of GLEANINGS matter, most of it excellent, and, as a matter of course, acceptable, but it hasn't appeared in GLEANINGS yet. Why? because we haven't room, although our journal is now enlarged to 44 pages. Many of the communications show evidence of painstaking care, but we fear only a small portion of them can be used. We are going to try to use the best part of them, however. If, therefore, you see the introduction and the tail end of your carefully worded and well-connected communication chopped off, don't feel hurt. Flowery introductions and appropriate "windings up" are not acceptable. We want

no apology for "inflicting" the readers of GLEANINGS with another article, but we want you to commence saying what you have to say at once. Complaints are already coming in because we are using the "other fellow's" articles, not so meritorious as some we haven't used. Please remember, it is our *privilege* to be the judge, and that we do fairly well is evidenced by our large and increasing subscription list. Please remember, too, that the circumstances are such that the rule of the "survival of the fittest" can not always be applied, although we try to use the best.

THE SILO AND ENSILAGE, BY PROF. COOK.

THE above is the title of a little book of 31 pages of reading-matter, written in Prof. Cook's happiest vein; in fact, while you read, those of you who have heard him at our institutes can imagine you hear the sound of his voice, and see the enthusiasm shining from his face. I have long been wondering why we did not have a book on ensilage, and one written by somebody who did not have the machinery for sale. Prof. Cook recommends the silo because he thinks it is going to be a great boon for farmers; and, so far as I can learn, I think he is right. The only criticism I have to make is the one I made in regard to Dr. Miller's book—a lack of engravings. I confess that I do not even now understand how the foundation of the silo is made, and I have read it several times over, while a simple rude drawing or diagram would make it plain to a busy laboring man, without taking much time or mental effort. I sincerely hope we may have a revised edition soon, with some pictures. The price of the book is 25 cts., and the size of the pages is 3¼ x 5¼. If more convenient you can order from us instead of from the author.

AIR-SLACKED LIME, IN CONNECTION WITH MANURE, AS A FERTILIZER.

UNTIL last season we had always had more or less trouble with club foot in our cabbages, and I began to feel considerably worried about it. Peter Henderson tells us, however, in his book, "*Gardening for Profit*," that lime or bone dust has proven to be a sure remedy with him. Now, inasmuch as we had seen club foot on some little plants in our plant-beds over the "new agriculture," we decided to give these beds a good dose of lime. Well, one day, when I was not around, the boys decided that they could kill two birds with one stone by raking in the guano and lime at one operation. When they came to mix the two together, however, with a sieve, their olfactories were greeted with fumes of ammonia that were almost like a dose from a smelling-bottle. However, they sifted the mixture over the ground and raked it in, and said nothing about it. When those cabbage-plants came up they had such wonderful vigor, and such a rich dark green, that I made quite a stir about it, and asked for further particulars as to the amount of guano, and how they did it. Then came out the above story. We tried it again with like results. I communicated the matter to W. J. Green, of our Experiment Station, Columbus, and he advised me not to put it in print until it had been more thoroughly tested. He succeeded in the same way, by mixing pulverized and sifted poultry manure with lime instead of guano. No club foot has ever appeared in our plant-beds since we adopted the above. But this is not all. Last fall, our neighbor, who deals in lime for plasterers' use, informed me

that he had forty or fifty barrels that had become so much air-slacked by the damp weather that he would sell it out to me cheap. By the aid of a manure-spreader we covered our richly manured lots with the lime until it looked white. We immediately harrowed it in and put on cabbages. The result has been good every time. The lime seems to have a remarkable effect in setting free the ammonia from stable or other manure so that it is available to the plants. But my impression is, that lime alone, without any manure, amounts to but little as a fertilizer. Now, besides liberating the ammonia it has another office. Our heavily manured soil is full of angle-worms; in fact, I have been troubled because it seemed to me they must owe their fatness and great size to the rich manure I have been buying around town. Well, in the fall we gave several plots a heavy dressing with slacked lime, and then plowed it into lands with deep dead-furrows between, to carry off the winter rains, so we could work it quickly in the spring. Well, after the first good rain, great fat angle-worms were found in those dead-furrows, dead, in such quantities that they could have been gathered up by the handfuls. The lime killed them. They crawled out in the dead-furrows; and the lime water, as it washed down, fixed them in good shape to give off their ammonia. This matter is already partly understood, as I have already noticed by the agricultural papers; but I am quite certain that it is not fully understood and appreciated in plant-beds and in greenhouses.

OBITUARY.

WE are pained to announce that Mr. Wm. H. Shane, who has been, perhaps, the most prominent raiser of comb honey in Medina Co., died on the 7th inst. Shortly after I succeeded in securing such large crops of honey by the use of the extractor, as mentioned in the introduction to the A B C book, Mr. Shane became interested in bees, visited me repeatedly, and asked me so many questions that I began to think that, if he remembered all my answers, he would know all I knew, any way. He was an earnest student, and soon became master of almost all that was known on the subject of bees. From the first he secured profitable crops of honey. Last season, and the season before, were no exceptions. Mr. Shane had a nice crop of honey, put up in beautiful shape, when almost every other bee-keeper in the land failed. While we lament his death, we rejoice to know that, like friend Raitt, while he loved his bees he loved his Savior more; and when the call came he was ready to go.

SPECIAL NOTICES.

We now have Dadant's Langstroth Revised, and can send them out by return mail. Price \$2.00. By freight or express, 15 cts. less.

160 SIMPLICITY ALL-WOOD BROOD-FRAMES FOR \$1.75, AT HIGHLAND MILLS, ORANGE CO., NEW YORK.

Here is a chance for some one in that vicinity. Who speaks first?

POULTRY NETTING AND FENCING.

We call the attention of our readers to our advertisement of netting and fencing, on the inside cover page of this number. Notice that prices are still lower than last year. We shall be pleased to mail a special 16-page netting and fencing catalogue to any one requesting it.

REDUCTION IN THE PRICE OF THE FIVE-PRONGED GARDEN-WEEDER.

The above implement is now furnished for 10 cents instead of 15, as formerly. If wanted by mail, add 7 cents for postage and packing. These are retained, to prevent rusting, and we think it pays to have half a dozen of them hung up in convenient places about our grounds.

CHOICE COMB HONEY AT 18 CTS. PER LB.

We have about 1000 lbs. of very choice comb honey in 4x4x4 sections, 7 to foot, put up 28 sections in a case, net weight of which is about 23 lbs. We offer it in single-case lots for 19 cts. per lb.; 5-case lots or more, 18 cts. per lb. It was produced by our neighbor W. H. Shane, who has so recently passed to his eternal reward.

12-INCH FDN. MILL FOR SALE IN CANADA.

We have at Cheltenham, Ont., one of our late 12-inch fdn. mills, sent from here a year ago, and has been used almost none. It is just as good as when new. We will sell it for \$30.00. The duty on mills to Canada is 30%, so you will make a saving of \$9.00 by buying this machine, besides the transportation charges from here there. Who will be the first to speak for it?

DISCOUNTS FOR GARDEN SEEDS, POTATOES, ETC.

As we are beginning now to sell a good many more seeds by ounces, pounds, pecks, and bushels, than formerly, we have decided to make the following discounts on large orders. But please bear in mind that this does not apply to five-cent packages of seeds. For all else in our seed catalogue we will allow a discount of 5 per cent on all orders of \$5.00 or over; 10 per cent on all orders of \$10.00 or over; 15 for 15 or over; 20 for 20, and so on up to 25 per cent off for \$25.00 worth or any larger quantity. In consequence of the great plenty of nice potatoes in our vicinity at the present time, we will, from this date on, allow a discount of 5 cts. per peck, or 25 cts. per bushel from prices given in our seed catalogue.

Later.—Since the above was written we have purchased two large lots of Burbank and Beauty of Hebron potatoes, suitable for seed, which we offer at 50 cts. per single bushel, or only 40 cts. in lots of five bushels or more.

OUR MARCH 1ST CATALOGUE, 68TH EDITION.

This has been increased in size to 44 pages by the addition of a rose-colored cover, thus giving room for more matter, and adding to its appearance a little more attractiveness. A careful observer will notice a great many changes over former editions, especially in the matter of hives. There are very few changes in prices, except in the Counter Store department, to which are also added a great many new cuts. Three pages relating to hives are entirely re-written, also the matter relating to sections; likewise that relating to circular saws, hive and section machinery. Our \$25.00 saw-table is advanced to \$30.00. Thin flat-bottom fdn. is reduced to 55 cts. per lb., and where it is taken in 25-lb. boxes the price is only 50 cts., and we furnish Vandusen's make, in sheets 16½ x 28, or 17 x 30. We shall be pleased to mail this catalogue to any of our readers requesting it; and if you have any bee-keeping friends and neighbors we will mail them a copy also, if you add to your request their name and address.

CLEVELAND'S ALASKA PEA.

I thought I had got through for the season mentioning all new things in the way of garden-seeds; but a notice of the Alaska pea, by our good friend A. C. Kendel, has reminded me of something:

The A. B. Cleveland Co., CLEVELAND, OHIO, June 26.
Gentlemen:—In reply to yours of the 23d, we would say the Alaska peas were given to a number of our most careful growers, and the reports are as follows: Planted at the same time and on equal quality of soil, the Alaskas in every instance were from two to four days earlier than any other variety, and were as good as any in quality. We predict for the Alaska a leading place among the first early peas.

A. C. KENDEL.

See also the following from the originator of the Chartier radish:

ALLEGHENY CITY, PA.

I made two personal trials of Alaska peas this season—early and a late sowing, and in both cases with similar results. In my trials I planted them with Landreth's Extra Early, First and Best, and Rural New Yorkers. In habit I find them of about the same height as the very extra-early varieties, but more slender in the stalks, and lighter green in foliage. They are in bloom nearly a week earlier than the others, and MA-

TURED FOUR DAYS SOONER. Crop all came in at two days' picking. Slightly more prolific than the others; quality very good. W. C. BECKERT.

In addition to the above we raised the finest patch of peas last year by sowing the Alaskas, that I ever saw or ever raised anywhere. They ripened up so nearly at one time that we cleared the ground at once and put cabbages in their place; in fact, the crop matured so suddenly—so much all at one time—that we were obliged to take it in wagonloads to towns to dispose of it. In fact, we had bad luck with peas, just about as we had bad luck with early potatoes. Did I never tell you about our bad luck with potatoes? Well, we expected 25 bushels from a little patch, and got over 100. We had so many Alaska peas that we could not sell them in Medina, and we could not sell them in the country towns, and so they went to seed, and we have now several bags full of beautiful seed—no bugs nor any thing of the sort. The pods are remarkable for their fine dark-green color, and this color holds longer after they have been picked than any other pea we have ever tried. Price, per packet, 5 cts.; per pint, 10 cts.; per peck, \$1.50; per bushel, \$5.00. If wanted by mail, add 8 cts. per pint for postage.

PRICE LISTS RECEIVED.

C. D. Duvall, Spencerville, Md., sends us a 12 page list of bees, queens, poultry, potatoes, and buckwheat.

G. L. Tinker, New Philadelphia, Ohio, sends us his price list of hives, sections, bees, etc.

C. M. Dixon, Parrish, Ill., sends out an 8-page list of poultry and bee supplies.

J. T. Wilson, Little Hickman, Ky., mails us his list of Italian queens.

S. S. Jordan, Hiramsburg, O., sends us an 8-page list of bees, poultry, and ferrets.

W. H. Bright, Mazeppa, Minn., sends us his 30-page list of apianarian supplies.

We have just printed for A. F. Bright, Mazeppa, Minn., a 16-page price list of poultry, bees, etc.

H. P. Landon, East Constable, N. Y., mails us a 4-page price list of bees and queens.

W. W. Bliss, Duarte, Cal., sends us his list of bee-keeping supplies, printed in the shape of a newspaper column, 3 x 28.

J. Lingensfelder, Akin, N. Y., sends us a 12-page list of queens and bees.

John Nebel & Son, High Hill, Mo., send us their price list of Italian bees and queens.

S. P. Yoder, East Lewistown, O., sends out a list of poultry and Italian bees.

CONVENTION NOTICE.

The annual meeting of the Western Ontario Bee-keepers' Association will be held in the Foresters' Hall, Chatham, March 20th and 21st, 1889. Come and bring your friends with you, as great preparations have been made for this meeting. The president of the O. B. K. A. will be present.

N. SMITH, Secretary.

FOR SALE CHEAP.

One second-hand Barnes saw with scroll attachment, in good order. One large Pelham fdn. mill, but little used; 300 good combs in L. frames.

6-7d GEO. E. BOGGS, Waynesville, N. C.

Cash for Beeswax!

Will pay 20c per lb. cash, or 23c in trade for any quantity of good, fair, average beeswax, delivered at our R. R. station. The same will be sold to those who wish to purchase, at 27c per lb., or 30c for best selected wax.

Unless you put your name on the box, and notify us by mail of amount sent, I can not hold myself responsible for mistakes. It will not pay as a general thing to send wax by express.

A. I. ROOT, Medina, Ohio.

HONEY COLUMN.

CITY MARKETS.

MILWAUKEE. *Honey.*—Honey in fair demand. Best 1-lb. sections, white, 17@18; second same, 16@17; best 1-lb., dark, 15@16; second same, 14@15. If damaged and leaky, 10@12½. Extracted, in bbls., white, 8@8½; in half-bbls., 8½@9. Amber, in half-bbls., 7@7½; dark, in same, 6@6½; white, in tin and kegs, 5@5½. *Beeswax.*—Nominal, 26@27.

Mar. 26. A. V. BISHOP,
Milwaukee, Wis.

ST. LOUIS.—*Honey.*—There is some demand for choice white-clover comb honey in 1-lb. sections, which is hard to supply, as there is none on the market. It would sell readily at 15. Common comb and extracted honey is plentiful; comb, 10@13. Extracted, in bbls., 4½@6, as to quality; cans, 5½@7½, as to quality; cans, 5½@7½, as to quality.

Beeswax, 21@22. W. B. WESTCOTT & Co.,
Mar. 22. St. Louis, Mo.

CINCINNATI.—*Honey.*—No change worthy of note from our last quotations. There is now no overproduction by any means, nor an overstocking of the market. Demand is slow for all kinds of honey, and prices low. We quote extracted honey at 5@8 on arrival; comb honey at 12@15, in the jobbing way. *Beeswax* is in good demand, and brings 20@22 on arrival for good to choice yellow.

Mar. 21. CHAS. F. MUTH,
Cincinnati, Ohio.

BOSTON.—*Honey.*—Our market is very short of fancy white honey, and sales are good. We quote: Fancy one-pound, 18@20. Same two-pound, 17@18. Extracted, 8@9. *Beeswax*, 24.

Mar. 22. BLAKE & RIPLEY,
Boston, Mass.

NEW YORK.—*Honey.*—There is no demand, except for dark extracted, of which supplies are small. Comb honey is all sold. We quote extracted California honey at 7½@8½. Basswood, 8@9. Cuban, in bbls., 6½. *Beeswax.*—Yellow, 24; half white, for foundation, 28. F. G. STROHMEYER & Co.,
Mar. 22. New York City.

ALBANY.—*Honey.*—Market about over for this season, with very little stock and very little demand. We advise bee-keepers to use ¼-pound sections; not only increases prices, but causes much greater consumption. H. R. WRIGHT,
Mar. 22. Albany, N. Y.

ST. LOUIS.—*Honey.*—Market unchanged. Could sell some in barrels at 6½@7½. *Beeswax*, prime, 21.
Mar. 22. D. G. TUTT GRO. CO.,
St. Louis, Mo.

KANSAS CITY.—*Honey.*—Honey is in fair demand. 1-lb. comb, 15; 2-lb., 13. Extracted, 8.
Mar. 22. CLEMONS, CLOON & Co.,
Kansas City, Mo.

DETROIT.—*Honey.*—Prices are somewhat lower; best honey in one-pound sections selling at 15@16. Extracted, 8@9, in tin cans. *Beeswax*, 22@23.
Mar. 22. M. H. HUNT,
Bell Branch, Mich.

OUT-APIARIES, NO. IV.

HOW MANY COLONIES IN EACH OUT-APIARY?

A GAIN we have a question to which no one is able with any positive assurance of correctness to give an answer. I think, however, the drift of opinion, of late years, has been toward a smaller number than in former years was thought possible. On page 905, GLEANINGS for Dec. 1, 1887, in reply to the question, most of the respondents agree on somewhere from 50 to 100, a good share of them having had no actual experience. Of those who have had experience, the answers show considerable diversity of opinion. Geo. Grimm says, "About 100 colonies." Dadant & Son say, "We do not want to exceed 100 colonies in any apiary." James Heddon says, "I keep about 200 colonies, spring count, in each of my apiaries." R. Wilkin says of Southern California, "About 300 colonies, provided no other bees are within three miles of you." E. France says, "We think our location will work 80 colonies, spring count, in each yard, profitably." There, you can read over those answers and then *guess* what will be right for you. P. H. Elwood says, "We keep from 70 to 100, spring count. Our neighbors crowd us some. Fifty would suit me best for best results, three miles apart, but we can't always put them just where we want them." Capt. Hetherington writes, "Our practice is to put 70 first-class stocks in an apiary—in a few cases 80, spring count. We find an advantage in about this number, as a man (with perhaps an assistant) will drive to such an apiary, *complete* the necessary work, and return the same day. With a larger number he could not do it; with less there is waste of time on the road." You see, Capt. Hetherington very wisely does not rest his decision entirely upon what may suit the

bees alone, but makes an important factor of the convenience of the apiarist.

Let us plan a little. Suppose you settle upon 70 as about the right number for a full day's work, and that you think there ought not to be more than 100 in one apiary. You have only one out-apiary, and a total of 200 colonies. You might put 70 colonies in the out-apiary, but then that would leave 130 at home—too many. Put 100 in the out-apiary and the 100 at home will be all right. You go to the out-apiary to-day and go through 70 colonies, leaving 30 that you must go and finish to-morrow. Manifestly, you might just as well go in the opposite direction to do those 30 to-morrow. So in general, whenever you have more than enough colonies to make a full day's work in each out-apiary, the best thing will be to start another apiary. Where you have the 200 colonies for your three apiaries, it is somewhat a question of convenience whether to keep 100 at home and 70 in one and 30 in the other out-apiary, or 100 at home and 50 at each of the others, or to divide the 200 about evenly between the three apiaries. If it makes no difference as to convenience of work, the last plan is probably the best. Please bear in mind, that although 100 may do well in one locality, 70 may do a little better, and 50 a little better than 70. "But," you say, "if there is clover enough to give 100 colonies all and more than they can do, how could a smaller number do any better?" Well, the clover doesn't last all the season. If it did there would be no object in having less than 100 in a place. Although the main crop of honey depends on a very few sources in one locality, as clover, linden, and perhaps buckwheat, yet there are great many other sources from which bees get a little, from some more, from some less. This varies throughout the season, there being a very short time, if indeed

there is any, when bees can find absolutely nothing upon which to work. Suppose at the poorest time in the season there is enough to keep only two colonies busy, then different times aggregating four or five weeks when 15 colonies can be kept busy, a few weeks when 40 colonies have all they can do, and so on, till we find a few weeks of clover when 100 colonies have all they can do. I think it is pretty evident that the two colonies occupying the whole field during the entire season will make a better average yield than the 100, and as you diminish the 100 your yield will gradually increase till the number gets down to two. Understand I don't say there will be any immense difference between 100 and 75, but still I think there will be some difference, and in making our plans we may as well keep in view the principle that the smaller the number the better chance each colony will have:

C. C. MILLER.

Marengo, Ill.

PURCHASING BEES.

QUESTIONS ANSWERED.

I AM requested to answer some questions in GLEANINGS, by one who says that he is a beginner in bee-keeping, he having been induced to go into the same by getting hold of a sample copy of the above-mentioned paper. In reading it he was seized with what is known as the "bee-fever," so has concluded to purchase some bees. He has subscribed for GLEANINGS, and thinks that I am just the one to answer his questions. In this last I think he has made a mistake, but will try, in brief, to do the best I can. He first asks what price he ought to pay for a colony of Italian bees in a movable-frame hive. Much depends upon the season of the year, and the condition of the colony. They are usually sold at from \$4 to \$6 in the fall, and from \$8 to \$10 in the spring. The reason for the difference in price is that, of late years, there seems to be much risk in wintering, nearly 75 per cent of the bees throughout all the United States being lost during one or two of our worst winters, while the average loss for the past fifteen years has not been much less than twenty per cent. If ten or more colonies are purchased of one party, the price should not be above the lowest figures given, for each colony. In an average season, and in a favorable locality, such a colony of bees should give 50 pounds of honey, besides one good swarm. The honey would readily bring ten cents per pound, or \$5, and the swarm should be worth \$4 without the hive, in the fall, which would nearly give the purchaser his money back, even if he lost the old colony, or fifty per cent of his bees, during the next winter.

DISEASED BEES.

He next asks, "Are bees subject to disease or epidemics?" There is only one disease of any account among bees, aside from our wintering troubles, and that is termed "foul brood." The cause of our wintering troubles, "doctors" do not agree upon, some claiming that continued cold causes it, others that it all comes through the pollen which the combs contain, while others talk of confinement, dampness, lack of ventilation, etc. Whatever may be the cause, our greatest mortality occurs during the latter part of a long, steady cold winter, an open winter being favorable to the successful wintering of bees, as the present season is

proving. Foul brood is of a different nature. The character of the season has nothing to do with it. So far no one knows the cause, except to guess at it. However, all agree, that the disease is carried in the honey. One bee-load of honey taken from a diseased hive to a healthy colony is sure death, in time, to that colony; so the greatest possible care should be used, where a colony is discovered having the disease. For symptoms and cure, see late volumes of GLEANINGS.

COST OF HIVES.

He next says he thinks of making a hive "14 x 22 x 11, with an outer shell for chaff, the whole to be covered with tin, and painted," and desires to know about what the cost would be. I should guess about \$4.50 for a single hive; while if 10 to 25 were made, \$3.75 each ought to buy them, including frames, sections, and all. But let me ask, "Why make such a hive?" It is out of the regular size, and could not possibly give better results than any of the hives now in use. There are four styles of hives in general use; the Langstroth, Quinby, Gallup, and American, any of which would give as good results as the one spoken of, and at much less cost, while any of them can have the chaff box fixed on the outside of it. Besides, all of the sections, frames, etc., to these hives fit the shipping-cases, extractors, and other conveniences, manufactured by most of our supply-dealers. A complete Langstroth hive can be bought for about \$2.00. It is one of the mistakes made by many beginners, in thinking that they can get up a hive "just a little better than the older heads have done," thus causing much complication in our business.

HONEY YIELD.

Then he wants to know, "How much honey should an Italian colony average annually?" Very much would depend on the location and management. Taking the United States together, the average yield among specialists is about 50 pounds per colony, spring count. Some years give double this amount, others very little or nothing at all. My average yield, for the past 16 years, has been not far from 80 lbs. to the colony, which I had in the spring. Best average (1877) was 166 pounds; poorest, about 30 pounds.

ALSIKE CLOVER.

Next he asks, "Does alsike clover suffer from drouth?" To about the same extent as does red clover, as it has a very similar root; but no kind of clover is infallible as to its honey yield. Very dry or very wet weather is against the secretion of nectar in flowers, and especially are cool or cold nights damaging. The last, in my opinion, are the cause of more failures of honey than all other causes combined, unless it be weeks of cloudy, rainy weather, together with high winds, which prevent the bees from leaving their hives in search of stores. There is an occasional season, when bees are kept at a loss in some localities, as all bee-keepers are willing to testify—seasons when they hardly get a living during the summer months, saying nothing about laying up stores for winter. However, the alsike clover is about as sure a yielder of honey as any thing which we have.

WAX-MOTHS.

"Is there danger of losing colonies by moths or other insects?" is the last question. The larva of the wax-moth is about the only real enemy which the bees have in the insect line. These feed upon the combs, and burrow through them, and in very

weak colonies often nearly or quite destroy them, changing them by consumption from the nice symmetrical cells for brood and honey, into a mass of webs and cocoons. However, there are no strong colonies destroyed from this source, especially Italians. In fact, where pure Italian bees are kept exclusively, these pests are rarely ever seen. Still, combs not protected by bees, especially those having pollen in, are always subject to their ravages, and should be looked after during warm weather. If signs of worms appear, the combs should be placed in a tight barrel or box, and fumigated with burning sulphur, having all fixed so that there can be no possible danger from fire. All combs taken away from the bees during the fall, winter, or early spring, are comparatively safe till swarming time, if hung an inch or so apart, so that the air can circulate freely through and about them.

G. M. DOOLITTLE.

Borodino, N. Y., Mar. 18, 1889.

WINGS OF INSECTS.

PROF. COOK TELLS US SOME WONDERFUL THINGS ABOUT THEM.

HERE is something in the very words "wing" and "flight" that stirs the imagination and wakes to life all the poetry and sentiment that there is within us. Even as practical people as you and I, brother Root, feel a sort of thrill and uplift as there comes to our ears, either upon the wings of memory or song: "Oh had I the wings of a dove, I would fly." Indeed, there are very few of us so stolid and inert that we are not roused, interested—yea, pleased—as we note the swoop of the osprey, the graceful curves of the swift-flying night-hawk, the easy, gentle motion of the listless butterfly, or the quick, arrow-like descent of the industrious bee. All of these are interesting, fascinating, and have claimed a large place in song and story all down the ages. In this article, however, I shall ignore sentiment and poetry, and aim to describe accurately only the insect's wing.

FIG. 1.—AN ENLARGED VIEW OF A HONEY-BEE'S WING.

The wing of the honey-bee, Fig. 1, is long, strong, and narrow. Such a wing, called falcate, indicates rapid flight. A bee or fly will rival a fast-running horse in speed. This same fact holds with birds. The hawks, pigeons, and night-hawks are noted for

their easy, graceful, and, upon occasion, their rapid flight. Their wings are all falcate. Our common meadow-lark has a labored, awkward, and lazy flight. Its wings are broad and short. Among insects the butterfly has a slow flight and broad wing.

FIG. 2.

The insect-wing consists of a thin membrane spread upon a framework of veins, or nerves. These veins are hollow, and so carry nourishment—blood and air—to the wing. The veins vary greatly in number and strength. Thus in the higher insects the veins are few and strong; in the lower, many and frail. In the lowest order of insects—*Neuroptera*—the veins are so numerous that they resemble lace, and we have the common name, lace-wings.

According to our modern philosophy of development, which now is universally accepted by scientists, we should expect much variation in organs as useful as are wings, and it is so. Thus the wings are useful in defining orders, and even lower groups down to species. Indeed, the names of the orders come from the character of the wings. *Hymenoptera*—the highest order, including bees, wasps, ants, etc., have four membraneous wings, hence the name, which means membraneous wings. So the word *Lepidoptera*, used to designate the order of moths and butterflies, means scaled wings,

and was given because of the shingle-like scales which adorn such insects. These scales rub off easily, and so the care required in handling moths, if we would keep our specimens in first-class order. The name *Diptera*—two wings—refers to the fly order, including mosquitoes, house-flies, bot-flies, horse-flies, etc. The word is very appropriate, as it means two wings. Thus we have *Coleoptera*, sheathed wings, for the beetles; *Hemiptera*, half-wings, for the bugs. The wings of the typical bugs are thick at the base, and appear like half-wings. Thus they are only half-wings in appearance. *Orthoptera*—straight wings—includes the crickets, grasshoppers, etc., whose front wings are long, slim, and straight. *Neuroptera*—or nerve wings—is very appropriate for the lowest orders, as is also their

common name of lace-wings. Here are found the dragon-flies, day-flies, ant-lions, etc.

There are five main veins in the best-developed wings. Thus (see Figs. 1 and 2) *a* is known as the costal vein, or nerve; *b*, the sub-costal; *c*, the medi-

an, or externo-medial; *d*, the sub-median, and *e* the internal or anal. The large open space in the wings of butterflies (Fig. 2) is called the discoidal area. In the higher orders the cells are all named. Thus, in the bee (Fig. 1), 1 is the costal cell; 5 the marginal, and 6, 7, and 8 the sub-costal, or cubital cells. These are very much used in classifying and describing different bees. Thus, the cells will be alike in bees of the same genus. All hive-bees will have wings as in Fig. 1; so the bumble-bees—*Bombus* will all have similar wings; and the carpenter bees—*Xylocopa*—etc. In entomology, then, we are ever studying these wings, for they are one of the most sure keys with which to unlock the curious relationships. Insects may and often do look very much alike; yet a study of the wings will show they are widely apart.

When insects like bees, wasps, butterflies, moths, etc., have two wings on each side, which act as one in flight, they are usually hooked together. In the honey-bee there are from eighteen to twenty-two of these hooks (Fig. 1, *h, h*), on the front, or costal margin of the hind or secondary wing. These hook into a fold of the front wing (Fig. 1, *s*). This fold is on the hind margin of the wing, which folds up and over. In butterflies and moths there is but one hook, which is close to the base of the wing.

Many insects are apterous, or have no wings. In such cases there are usually structural indications that the ancestors of such insects possessed organs of flight. In these ancestors, owing to changed habits, the wings were not used, and nature snatched them away. I am sure nature abhors a useless member, whether of an animal or of society. We can often see nature whittling away these organs. Thus we often see insects with wings weak and abortive. The insect, from its mode of life, has ceased to use its wings; and nature says, "If you tie up my gifts in a napkin, I shall take them away." Just as nature says to us, "Think, study, or soon you will have no brain power for thought and study; exercise, or soon you will have no muscles to work with." What a unity—a oneness of plan—runs all through nature! Even the study of nature alone, proclaims that there is *one* God, and he is in all and over all.

The rate of flight in insects is marvelous beyond comprehension. The bee flies often twenty miles an hour, while very tiny flies will often keep abreast of a horse in full speed. Landois, judging from the pitch, finds that the bee's wing may vibrate 440 times per second. While there is no doubt about the truth of this statement, the fact baffles comprehension. The sole use of the wings of most insects is for flight. A few insects, however, like the crickets, locusts, and grasshoppers, use them to voice their feelings. The love-note of the grasshopper, cricket, and katydid, is produced by motions of the wings alone, or of the legs and wings. Thus the insect chorus which sounds by day and night during the warmth and sunshine of summer and autumn is but the love-songs of these myriad Lilliputs. These songs which "rasp the silence" are sure signs that sentiment and emotion reach even to the lesser forms of animal life; and while they are no proof that insects possess ears, they do show clearly that insects have a very delicate sense, whereby they take account of vibrations.

Agricultural College, Mich.

A. J. COOK.

Well, old friend, you have given us one of the grandest talks above that ever came

from your pen. I did not know before that you felt a thrill whenever a winged insect passed by; and I have sometimes thought that I was more imaginative than most people, when that thrill comes to me over and over again, suggesting that somewhere or some time we too shall be wafted through the air. I do not know whether it is coming through machinery or by the aid of some great bird that shall be bred up on purpose to carry people through the air; but I am certain that God, in his infinite plans, has this in store for us. We breed horses for great burdens, and also for speed—why not birds? By the way, who will tell us the most fit bird to commence with? I suppose the brothers and sisters down south will laugh again if I suggest turkey buzzards as being somewhere in the line. They are gentle, and have enormous wings. They can already carry a considerable burden, for I have seen them do it. Friend Cook, there is one more problem that has troubled me sorely, that I do not find touched in your talk at all. Why does an up-and-down motion, or, in fact, any sort of motion of a flat wing, like the wing of a bee, carry it aloft in the air? I have read some learned papers on this subject, but they do not satisfy me. I can understand how a bird flies, because the wing is concave; but why does the paddling motion of a butterfly with its wings enable it to soar aloft? Every spring, when butterflies come around, I watch and ponder; but I have not got any further than the old gentleman who replied to his good wife on a various lot of problems, "Case it does." The motion of the wings does enable them to fly, but I do not see why. Then, again, there is a species of bugs that have a coarse dark overcoat under which they tuck their gauzy wings to keep them nice. It always reminds me of a city belle putting away her gauzy laces and trimmings in a big Saratoga trunk. When these bugs alight you would think they could never tuck the filmy wings under these black shells at all; but they fold them all under very quickly and very neatly; and when the sun comes out they manage in some way to get them spread without very much fuss or bother either. When fighting squash-bugs alone, sometimes I have been tempted to waste time in seeing the little rascals fetch out their wings when I got at them. My daughter, Mrs. Calvert, has a pet canary bird that flies all over the house. It alights on her head and shoulders, flits from one hand to the other when she is doing her work, and a study of the deft and skillful way in which that bird uses its wings awakens that same thrill you have mentioned. The bird has become playful, and it is the wonder of "Root village" to see how much sense can be packed away in such a little mite of golden feathers. No doubt it is true that God takes away our talents that are unused; but don't you forget, dear friend, to mention that the reverse is also true—"To him that hath shall be given"? Just as sure as we begin to develop the talents we have, a vast extent of unexplored region begins to unfold itself before our wondering eyes; and it is right in this

line that I believe we are going to be able to enjoy flitting through the air by and by. Our proof-reader suggests another thought. Here in Medina just now it is exceedingly muddy. His thought is this: That it seems to be too bad that *man* should be compelled to trudge through the mud, while even the *turkey buzzards* fly with such wonderful ease through the air.

RAMBLE NO. 13.

AMONG THE MOUNTAINS; RUINING THE HONEY MARKET, ETC.

"It's all very well for poets to tell,
By way of their songs adorning,
Of milkmaids who rouse to manipulate cows,
At five o'clock bright in the morning;
And of mooney young mowers who bundle outdoors,
The charm of their straw beds scoring,
Before break of day, to make love and hay,
At five o'clock bright in the morning."

THE Rambler considers it very unwise and unhealthy to get up before sunrise. This is an excellent rule to follow in the winter, and it is with regret that we see the days lengthen; but "old Sol" is inexorable, and he peeps into our window a little earlier every morning, and bids us arise. It is a noticeable fact, that those people who sleep in church are the ones who

Get out of bed, their house, and their head,
At five o'clock bright in the morning.

It is far better to take the needed sleep in the morning than to take time for naps during the busy hours of the day. I am led to thus discourse upon early rising because I thought the sun had forgotten to shed its morning beams on the Virgil mansion. Getting tired of waiting, I went out to see about it; and after waiting a little I saw a glorious sunrise over that rocky cliff.

"HELLO, OLD SOL! IS THAT YOU?" SUNRISE AT MR. VIRGIL'S.

I found Bro. V.'s headquarters in a small but convenient shop. The most of the work of getting out portions of hives, crates, etc., was done on a

home-made foot-power saw, which showed evidences of much hard work. The apiary did not look so bright as it would if more paint had been used, but it was evidently laid out for convenient work; and as the proprietor is after money and no poetical fixings, perhaps it is just as well. If the owner is pleased, the Rambler certainly is.

The honey-house was a neat little affair, crammed full of implements, and a few crates of very fine honey. Bro. V. keeps up with the times, and produces A No. 1 comb honey, and does not make much effort on extracted honey. Cappings and all pieces of comb are thrown into a barrel, and a heavy maul pounds all into a solid mass, proof against miller-worms, and in time it is rendered into beautiful wax, at which business Mr. V. is an expert. He is also an expert bee-hunter. Several swarms are secured every fall from the surrounding mountains. Cellar wintering is practiced, and, owing to the lowness and level nature of the land, the water floods the cellar at very inconvenient seasons; and perhaps early in March all hands have to work lively to get the bees out of the cellar to prevent total destruction. Still, Mr. V. has had very good success in wintering. I think I suggested the digging of a cave into that rocky cliff for wintering, which could be easily done.

After breakfast we struck out for other bee-keepers in the vicinity.

"IT DON'T PAY; I'M GOING TO NEW-BRASKA."

Mr. —, whom for convenience I will call Jones, we found with a score or more of colonies. This man's methods conflicted somewhat with Mr. V.'s. Several bee-keepers in this vicinity find market for their honey in Whitehall, a village of about 4000 inhabitants. Jones lives the nearest, about a mile; and as soon as a few pounds of honey are ready to come off, he trots it into the village and sells it at a remarkably cheap rate, demoralizing the market for those who have a better quality of honey in better shape. As a result there is any thing but good feeling toward him from those who have honey to sell in the same market. Mr. Jones's bees were mostly in box hives. He loved the bees, and wished he could work with them all the time. Not attaining much wealth, he wanted to sell out and go to "New-braska." The disease seemed to have a strong grip on him, and, from Mr. V.'s remarks about what a glorious country is found in the West, I had no doubt but he wished the "New-braska" fever would take his neighbor far away.

About three miles from Whitehall resides Mr. C. Beckwith, another of those enterprising young men who have tried many things and found much vexation of spirit where, to the imagination, things

were all lovely. Mr. B. had about 100 colonies; had purchased a steam-engine, saws, many tools, had invented a hive with a frame differing in size from any other he ever saw; and now, after getting up to 100 colonies, he wanted to sell out! Reasons, a large farm to manage, and he found raising potatoes, fighting bugs, milking cows, fattening pigs, or hunting woodchucks, all a bigger bonanza than bee-keeping. "Come, make me an offer for the whole business. Why, that pestiferous Jones, down by the toll-gate, has ruined my trade in the village; and if he wants to go to Neu-u-braska, we had better bundle him off to-morrow."

Nothing would console our friend Beckwith, and we left him, considering that nothing could remedy these cases of conflicting interests but co-operation, or the purchase of the stock of the mischief-maker. We find that, when the interests of many bee-keepers center in one moderate-sized town for the sale of their product, there is more or less conflict, resulting, perhaps, in a few, who have a good standard article, in withdrawing entirely from the local market and shipping to commission men.

I would ask Mr. J. A. Buchanan, who has given us much interesting information upon the sale of honey, if he has had this damaging competition in his experience, or how he could overcome it if it should arise. The Rambler has had some experience in selling honey through a farming community, and thus far has had no competition; but even if there were, we should be no worse off than nearly every salesman of other goods of whatever description. I find the best plan to sell honey is to combine it with the sale of some other articles, and keep the cart going all the year round. "A continual dropping will wear a stone;" so continual trips will wear away a big pile of honey in a year. If all the honey in a certain district were placed in the hands of a competent local traveling salesman, there would be but little to go to commission men. Hurrah for the honey-peddler, the sweetest man on earth! That's what all the gi-gir-boys say about the

RAMBLER.

P. S.—In relation to the age of pigeons when ready for market, I do not know. The authority from whom I got my information in relation to growth was a fancier, and did not grow pigeons for sale. I notice there is a difference of opinion between our prominent authors in respect to the preparation of food for the young bee. Cheshire claims that larval food is secreted by a gland located in the head of the bee, around the eyes. Cook claims that it is not a glandular secretion, but chyle, and that the glands merely secrete a ferment that aids in digesting pollen. Whoever may be right, we know there is a concentration of food, and in the pigeon we have an unquestionable demonstration of it on a comparatively large scale.

Thanks for your kind invitation to that California trip. Nothing would please the Rambler better than a visit to the Golden Gate; and as I have relatives in Oakland, I fear my visit would be prolonged should I get there. The editors of GLEANINGS are cordially invited to come east. The Rambler and many others are ready to extend such fare as they have, and the best of it, to those they have

known so long. Yes, that is the Rambler with his hands on his knees, but that can not be the R. at the blackboard—the person is too aldermanic. The R. wears a smaller vest. That man weighs 200 lbs.; the R. only 140, and 5 ft. 10 inches. R.

FIXING FOR HONEY EXHIBITS AT FAIRS.

A BRIGHT SUGGESTION FROM FRIEND HOLTERMANN.

FRIEND ROOT:—I was much pleased with Dr. Mason's articles on the above subject, and also with the display of honey and bee-keepers' supplies at the Ohio Centennial. There is one point, however, which I did not like at all at Columbus; and now Dr. Mason has an illustration of this objectionable feature—"so, there now!"

The regular shelves (or irregular, if you like) as illustrated are unsightly, and particularly so if not completely covered by the exhibit. I have used them, and now avoid them, and try to break the monotony of the show as far as possible. In my estimation, a platform four or more feet deep, and the height of an ordinary table to start on, is desirable. Put your first shelf on this, as in Dr. Mason's illustration, but run it back the same distance as the table. Then place some of the boxes used in shipping goods to the exhibition (height about 15 inches and the right size) on the shelf thus described, and lay the boards which form the tops of crates for Stanley honey-extractors (being eight-sided as here shown) on top of these boxes. Upon

these eight-sided boards place other but smaller boxes, and then put on the top-board of the crate for an ordinary extractor, which is the same shape (8-sided) and much smaller. On top of this, put another box. Then toward the right and left ends of the shelf I build another pyramid, only smaller, and cover all with white paper (I claim there is no better color for covering), and then arrange my exhibit. The pyra-

HOLTERMANN'S ARRANGEMENT OF SHELIVING FOR EXHIBITS.

mid I can make still higher by placing upon it first a 10 gallon can, then a smaller; and on top of all, glasses with honey. It breaks the monotony of these shelves; and if you mix in comb honey in crates, which is desirable, a very neat display can be made. A few pots of flowers (the pot covered) add greatly to the display.

You can put a number of your cases in a safe place—quite an item when you would otherwise have to put your cases with thousands of others, and can not find them at the close of the exhibition, and realize you are not at home, where you could replace them.

There was a monotony about the extracted-honey

display which I did not admire. It is very difficult to break this with only extracted honey, in any case, but it is well nigh impossible with shelves. As before stated, the monotony can be broken nicely with a photograph, say of father Langstroth, then individual bee-keepers, or some of the many groups, diplomas received at previous exhibitions (of course these diplomas must be put in after the prizes have been awarded); cakes of nice wax, and flowers in pots, or cut flowers. It is a very good plan to bring along a honey-extractor, and combs with half of the combs on each side uncapped, and out of which you have extracted the honey previously. In this way you can show just how extracted honey can be secured. When bringing material for display, bring what is lightest, and will make the most display after considering their advantage otherwise. Articles bad for packing, avoid.

Brantford, Canada.

R. F. HOLTERMANN.

Friend H., I believe you are right. I have a great many times felt what you describe, when visiting exhibits at fairs. The same thing is also true in the arrangement of grounds, greenhouses, and gardens. A little bit of variety, even if nothing more than an octagon pyramid between two square pyramids, often gives a peculiar grace and charm to the whole arrangement that would be entirely lacking without it.

ATTIRE FOR THE APIARY.

MRS. HARRISON GIVES US SOME SUGGESTIONS IN REGARD TO THE WAY A BEE-WOMAN SHOULD DRESS.

I FEEL a little slow this morning, so I sit in the rocking-chair, with GLEANINGS in my hand, and admire Rambler in his pretty checked suit. I really believe he has a bow of natty ribbon at the bottom of his pants; perhaps the button was off, so he tied one around to keep out the inquisitive insects.

How I envy him that suit, because it is light, cool, and handy! I might raise "von tollar" and get one "zhust a fit;" but if I donned it, a policeman would whistle for the patrol wagon and take me to the calaboose on the double-quick. I should think the bees would investigate the inside of the blouse, as it appears so loose at the bottom; but then a belt buttoned around would easily prevent that. I've tried hats and veils many times, with the result of a pretty sore chin and neck. I could protect my nose, but I could not fasten the veil so that, in working, the bees would not sting through. The brim would keep the veil far enough from my face; but in stooping the bees would sit down on the back of my head and form a chain around my neck.

I want to dress according to my work, whether it is in the apiary, washing, or blacking a stove. In the apiary I have to guard against heat and stings. I have for many years worn a health-reform costume, with the idea in view of clothing the body so as to promote an equilibrium of circulation and warmth. In warm weather I wear a cotton suit, consisting of waist and drawers; formerly I wore them made in one garment, but I much prefer them separate. The waist is high neck and long sleeves, and is supplied with buttons at the bottom, for to button the drawers upon. The drawers reach to the ankles, and are kept in place with a

strap passing under the foot. I'm clothed when I have on these garments, and I've had bees creep up from my feet and come out at the neck, without stinging. The hose are drawn up over the drawers, and at times I fasten the sleeves tightly around my wrists. If I go to work in the apiary with slippers on, I generally have cause to regret it, as I get stung in the feet, so I wear a leather shoe.

When working in the apiary, if I had to wear corsets, bustle, and two or three skirts, I should cry out about bee-keeping being too hard work for women, just as Mrs. Chaddock does, and throw mud at those who venture to attempt it. I keep my bee-dress hanging in the honey-house; and when I work in the apiary I take off my house dress, hang it up, and put this on. When the thermometer is playing around one hundred in the shade, I wear a skirt and linen sacque. I put on my wire hat, then the sacque which covers up the cape, so no bees can possibly get at my head, fasten the sleeves tightly at the wrists, then the skirt. I do not let the bottom of the sacque hang loose; if I do not wear an apron tied around me I put the skirt-band over it. I'm not dressed for company, but for work in the apiary, protected from stings and from being overcome with heat. Should company call, or when dinner is ready, I retire to the honey-house, wash, and put on my ordinary clothing, which takes but a moment. I'm warm, and I need more clothing when I sit in the shade.

Women who are not very young or strong can do a great deal of work in the apiary if they manage well. We have about thirty colonies of bees on the east side of our house, and they are in the shade after two o'clock. If there are sections to be put on or removed, or any other work to be done here, I do it when the hives are in the shade. There are other colonies that can be worked with in the morning, when they are shaded. I could not work with the hot sun pouring down upon my head.

We run our apiary for comb honey, but I extract several hundred pounds every year, and in a quiet way, so that the family are not aware of it. When I know where I can get some honey to extract, I take my tin comb-basket, remove the filled combs to it, put empty ones in their place, and carry them to the honey-house. When I've extracted them I put them in the bucket, snap the cover over the uncapping-can, cover up the extractor, change my clothes, and no one knows what I've been doing, but find out next fall and winter. I never do any big day's work in the apiary, unless I am driven to it in swarming time.

MRS. L. HARRISON.

Peoria, Ill.

My good friend Mrs. H., I am glad you have given us these suggestions. As soon as I saw what Rambler had said, I remarked at once to Ernest that somebody should give us some suggestions for a woman's suit. I suppose you know that I do not at all believe or advocate that women should dress as men do, therefore I am glad you have such strict "police regulations" in Peoria. I think you have got the idea of a bee-dress for women exactly, if I understand you. A woman can dress just as comfortably as a man, and she can protect herself from stings; and then, for the very reason you give, she should have something light to throw over this working suit to make herself look womanly, and that she may not attract attention from passers-by.

Just one thing more, my good friend: If the police regulations could only "regulate or restrain" (prohibition would be out of the question, I suppose) the growing evil of—not intemperance this time—but those very bustles you have alluded to, Uncle Amos would feel happy, even if no one else did.

THE STARVING COLONY.

THE ALFILARIA.

Starvation's form sat grinning at their door—
Their only guard—what need had they of more?
They called a meeting then, in Sally Hall,
To see if they had means to live at all.
An aged warrior cried, "My race is run,
While many more of yours have just begun.
Three cells are left—a scanty store, I ween,
And I would move we leave them for the queen.
We may die slowly—singly—one and all—
But our dear queen must be the last to fall."
"I charge you now," she cried, with pleading eye,
"To tell us plainly if we have to die;
Tell us what foe we have to face or fear;
And quickly, too, or it shall cost you dear!"
"Arm! arm!" he cried, "'tis not the crack of doom
I come to tell; the 'filaree's in bloom!"
A shout went up that made the welkin ring,
And every bee began to *whet his sting*.
A round applause was given that shook the floor,
When all at once a scout stood at the door;
And he had that within his eye which told
That he had potent news to there unfold.
"Arm for the fight," he cried; "each warrior, arm!"
Each stood aghast, with terror and alarm!
And then the queen, to aggravate their fears,
Stood up and burst into a flood of tears.
The fainting queen fell helpless to the floor,
While all rushed pellmell for the door.
And then they raised the song they always sing,
When every bee is *every inch a king*.
The scout and queen were then a happy pair;
For now she sang and wept for joy there.
But, hark! The first-returning song she hears,
And, starting up, she wiped away her tears.

I.

"O my queen mother! I come, I come,
Over mountain, hill, and dale,
Through the deep and silent vale.
Every thing was dry and stale—
I thought the very skies looked pale."

II.

"O my queen mother! I come, I come—
I hied me to a vineyard bare,
Where oft the bloom is rich and rare—
Found only desolation there,
As I swept through the silent air."

III.

"O my queen mother! I come, I come;
But further on—on lower ground,
A lovely green rosette I found—
Not only one—but they abound
In great profusion scattered round."

IV.

"O my queen mother! I come, I come;
I found the purple star was there;
And the green rosettes, so rich and rare,
Are coming up in thousands, where
The ground of late was stark and bare."

V.

"O my queen mother! I come, I come;
And here I now present to you
This shining drop of nectar new.
The purple star that's always true,
Now gives her first fruits unto you."

VI.

"O my queen mother! I come, I come;
A hundred now behind me stand,
With nectar from the vineyard land.
A sweet surprise the scout had planned
When we lay on the starving stand."

The alfilaria is one of the most nutritious grasses of California. It comes up first in well-worked, clean ground, in the shape of a green rosette. The rosette looks as if it were made out of small fern leaves. In the middle of it first appears a small purple star; then another and another, until the grass loses the shape of the rosette, and bears hundreds of flowers. It lasts until the black sage blooms. It lies so flat on the ground, when it first blooms, and the bees are so thick on it, that I have been often afraid of trampling them to death in walking over a patch of it.

Bees on this coast, so far as I have handled them, are more vicious and vindictive in the honey season than at any other time. In the dry season and in the fore part of the winter, they hang in the upper story of the hive, many times three inches deep. They seem to be listless and lazy, and are ashamed to look you in the face. I do not believe that over five per cent are in the air, at any one time during the whole time from the close of the honey season until the opening of the flowers the next year. I have thought that they keep only scouts out during all this period. Two or three puffs of smoke will settle them at this time, but it takes volumes of it to take off honey, or to go into the brood-chamber during the honey season.

J. P. ISRAEL.

Olivenhain, San Diego Co., Cal.

Why, friend I., the very mention of alfilaria, especially as you put it, brings up many happy memories; and I want to say to our readers, that, when I first set foot on the soil of California, there was not a green thing nor a living thing to be seen on the mountains, and hardly any thing in the valleys—that is, without the aid of irrigation; but under the influence of a summer rain, in just a few hours the whole landscape became clothed with green, and a great part of the green came from the 'filaree. When I was a jeweler we used to have a certain kind of work which we called "filagree." Well, the filaree suggests just that. It comes up as grass, and I am told it makes excellent feed. The beautiful bright green has a sort of mellow golden tint that is sure of captivating any one who loves nature. In the most protected valleys I watched for the largest specimens, hoping I might catch a glimpse of the tiny flower, but I didn't; and inasmuch as there are thousands of acres of it, and it comes up spontaneously everywhere, I don't wonder that the bees rejoice when it comes in and saves from starvation perhaps thousands of colonies. I have so many times watched the bees in their rejoicings when the first honey came in from the soft maples, that I can readily imagine your poem to be true, at least in sentiment.

CAPT. HETHERINGTON.

AS A BEE-KEEPER—CONTINUED.

CAPT. HETHERINGTON is a skilled mechanic, and makes all of his supplies, including extractors, box-making machines, etc., even to the three dozen wheelbarrows he uses in his different bee-yards. The material is prepared, ready to put together, in his mill, five miles from home. He prefers, when he has to oversee a dozen or more men, and keep their machinery in order, to put that distance between himself and those who would call him from his work. His honey-boxes, clamps, cases, etc., are models of perfection and neatness. His packing-cases are of the whitest basswood, papered inside, so that there may be no leak, and the boxes rest on cross-cleats, so that the drip may be kept from them. At the Centennial his exhibit of 3500 lbs. in single-comb sections, together with a variety of ornamental packages of honey and wax, was admired by all. The exhibit was built up to represent the turreted front of an old castle, so arranged as to allow the light to pass through in the freest manner; the whole surmounted by the flag under which he fought for three long years. The highest prize was awarded him—a medal and diploma. Two years before this (1874) he had made a large shipment of comb honey to England, which Mr. Quinby said was the first sent abroad in quantity. At this early date he recognized that the relief for an overstocked market here must be sought abroad. It is to be regretted that our wholesale dealers have not persistently followed up this exportation, as there are but few difficulties to overcome, aside from the national prejudice of the average Briton that foreign products are not quite as good as home productions. Our climate is drier, and we have a better proportion of sunshine than England, conditions which should give our honey a superior body and flavor. While Mr. Cowan, editor of the *British Bee Journal*, did not admit this, other distinguished visitors have done so, and it is confidently expected that, in the not distant future, the early expectations of Capt. Hetherington will be realized, and that Great Britain will demand some of the products of our apiaries.

Messrs. Cowan and Young, on their recent visit to this country, recognized Capt. Hetherington as the most extensive bee-keeper in the country; and on his return, Mr. Cowan stated, in an address to the British Bee-keepers' Association, of which he is the recognized head, that at Cherry Valley, N. Y., he "met the most extensive bee-keeper in the world." This October his colonies number about 3000, located in twenty-two apiaries. The management of these large numbers must necessarily be in a systematic, wholesale way, to which we may fairly apply the word extensive rather than intensive. His results per hive should not be expected to equal those who keep a smaller number, cared for with the closest possible attention, although it can be said they do not fall far short. In a good many of the details of business, however, the word, "intensive" might very appropriately be applied, for in the mechanical perfection of his supplies of all kinds, and in the neatness and order displayed in every branch of his business, even to the minutest detail, he far surpasses the average keeper of a dozen hives. So well does he look after the details of his business that it would be difficult to inquire for any implement or article used, or rem-

nant left within a year, but that he could tell you where to find it.

As soon as possible after giving his bees a flight in the spring, he moves them away to his out-yards, which are situated from two to twelve miles from home. After this they are visited as often as may be necessary, at intervals varying from two days to two weeks. Usually, however, during the honey-gathering season, at some time between Monday morning and Saturday night, they are all seen. He hires a plot of ground on which to set them, and takes all the care of the bees. No one looks after issuing swarms, because he has no such swarms worth looking after. For some time after adopting the new Quinby hive he labored with Mr. Quinby to prevent swarming by giving shade, young queens, and plenty of room in surplus and brood apartments of the hive; and in 1868 he succeeded in preventing all increase from the 150 colonies then under experiment. What worked well in one season, however, did not succeed in all, and it was not until he practiced removing the queen that he was entirely successful in controlling swarming.

For some years he has used the T clamp and one-pound sections, glassed or unglassed, as the market demands. In the fall he moves his bees all back home, when they are weighed, their stores equalized, and they are prepared for winter. The principal forage at Cherry Valley is clover, basswood, and buckwheat, which last, being largely stored in the brood-apartment of the hive, usually insures sufficient stores for winter.

In connection with his last attempts at outdoor wintering, the captain experimented quite largely with plaster of Paris as a material for bee-hives, it being an excellent non-conductor of heat, and a good absorbent of moisture. But he soon discovered that, in common with the absorbents he had before used, in proportion as it became saturated with moisture it lost its non-conducting properties. He therefore, after the most thorough trial, abandoned, with almost all kind of hives and all kinds of packing, outdoor wintering, as unsuited to his severe climate, where a five-months' confinement to the hive is sometimes experienced. In this high mountainous region, successful wintering has been the most difficult point in practical bee-keeping, and perhaps always will be, as the honey-bee is indigenous to warmer climates, and, when removed to long winters, it does not bear confinement well unless every condition is perfect.

The captain finds it best in the fall to persistently weed out all swarms not up to a high standard of excellence. Some years as many as one-third are thrown out as unfit for the cellar. He takes personal supervision of this preparation for winter, and not long since he informed me that either he or his brother had examined every swarm as to quantity of bees and amount of honey. The writer, after spending some time in looking through his bee-yard, concluded this was the best lot of bees he ever saw. There were no second-quality swarms, and an old queen was the rare exception, for Hetherington has a decided preference for the first-year's work of a queen.

The captain is not at all satisfied with his wintering, notwithstanding his success of late has been much better than that of the average bee-keeper. In the spring of 1881 he took a carload of his weaker swarms as far south as Philadelphia, in order that they might avoid the chilling winds of the

North, and be benefited by the early forage and warmth of the South. The experiment was a success; but on account of wearing work he has since preferred to unite his weakest stocks early in the spring.

P. H. ELWOOD.

Starkville, N. Y.

To be continued.

THE CENTENNIAL HONEY-EXHIBIT.

DR. MASON'S PYRAMID OF HONEY; A GLIMPSE AT A FEW OF THE BIG BEE-GUNS.

FRRIEND ROOT:—Under the circumstances it seems to me that this picture, taken in a closed building, and with but little light, is a pretty good production for an amateur. It represents a portion of one of the honey exhibits at the Ohio Centennial at Columbus last fall, and is decorated by the faces of some bee-friends.

The man at the right is Mr. C. E. Jones, of Delaware, O., one of the exhibitors whose exhibit of

Mr. N. W. McLain, known to all your readers as the one having charge of the Government Apiarian Experimental Station in Illinois, and at his right sits "yours truly," who got a "racket" from Ernest because of his "wiggling" so as to spoil the face; but the splendid picture of the indefatigable worker, and editor of the *American Bee Journal*, Thos. G. Newman, makes up for any deficiency in mine.

In this picture, near the lower left-hand corner, is shown a portion of one of the side platforms on which the exhibits were placed. The wire poultry-netting, which I have mentioned before, is nicely shown, with three of the posts that held it up. Near the top of two of the posts were tacked cards of your \$1000 offer in regard to comb honey made by machinery. It seems to me it would be a good plan to have a goodly supply of these tacked up in conspicuous places at every exhibition of honey; and it might do no harm to have them on every crate of honey that leaves the producer's hands.

A PARTIAL VIEW OF THE APICULTURAL EXHIBIT AT THE COLUMBUS CENTENNIAL, WITH SOME OF THE PROMINENT BEE-MEN IN THE FOREGROUND.

comb honey, etc., I mentioned in my last; and to his left stands his little boy, Charley. Next to Mr. Jones is the one I have once mentioned as known by "our company" as "Uncle Aaron" Goodrich, of Worthington, O., an enthusiastic bee-keeper over 75 years old, one of the largest exhibitors, and who was awarded first premium on display of comb honey. Next to "Uncle Aaron" is shown Mr. J. Y. Detwiler, of New Smyrna, Florida, formerly of Toledo, O., who, at an expense of \$80, came to attend the meeting of the N. A. B. K. Soc'y, and to see the Exposition. He also acted as one of the judges in the Bee and Honey Department, H. D. Cutting, of Clinton, Mich., being the other judge. Whether it pays or not to attend bee-conventions unless one "has an ax to grind," as Mrs. Chaddock has said, Mr. Detwiler had no ax to grind, and he was one of the active ones in the convention. Next to him is

In this exhibit, a portion of which may be seen at the top, were shown about 150 honey-producing plants, mounted on strawboard, some of them being hidden from view by the persons in front, as was also a display of honey vinegar and different kinds of honey. Over Mr. Newman's left, and my right shoulder may be seen points of the nozzles of Bingham smokers, an assortment of all styles and sizes of which were here shown, with Bingham, Novice, Muth, and Murphy honey-knives. The Bingham smoker and honey-knife were awarded first premiums. In the lower left-hand corner is shown the gearing and a portion of the top of a Muth honey-extractor, exhibited by Dr. Besse.

The exhibit of honey shows for itself. The honey on the pyramid was linden (basswood), and, being very nicely candied, it made a pretty display, and was so frequently called sugar by visitors that

a sign was placed on it, as may be seen, which said, "Candied Honey. No Sugar Here." A few bottles of it had been drained and then stirred, so that not even an expert could tell that it was *not* sugar, without tasting. The editor of the *A. B. J.* refers to it in the number for Nov. 14, 1888, page 739. The pyramid was originally designed to be eight square; but as only about one-half of it would show, the back half was left off. The next week after the visit of those in attendance at the convention, your young man, W. B. Weed, took the pyramid in hand and decorated it and rearranged the honey, and made it a "thing of beauty." In the back concave side of the pyramid your men had a shelf on which they did their writing and kept their stationery, etc. In the rear of the straight shelves they had a bedroom and a wardrobe, the whole being inclosed by a door, as shown; and over the door, and but little shown in the picture, the sign, "Medina Headquarters." On the brace, near the upper central portion of the picture, a sign says, "Honey-producing Plants;" and above that another, on which may be seen, "Exhibited by Dr. A. B. Mason, Toledo, O."

To the left of this picture, and on the same platform, was a large exhibit of comb and extracted honey on shelves, 20 feet long, and extending nearly to the top of the side of the building. This belonged to "Uncle Aaron," whom I have before mentioned. In connection with this he made a fine display of very yellow beeswax, molded in different forms and sizes. It, of course, took the "red ribbon." He also had a display of five gallons of the lightest-colored honey vinegar I ever saw. It was as clear as the best water, and attracted much attention.

To the left of Uncle Aaron's exhibit was that of Dr. H. Besse, of Delaware, O., occupying 20 feet of the platform, and consisting of comb and extracted honey, beeswax in the form of round columns, foundation-mill, smokers, honey-knives, bee-literature, etc. On the platform in the center of the building I also exhibited a Given foundation-press on which foundation was occasionally made, to show people how it was done. Also a U. S. honey-extractor, with duplex reel; and being, as you know, an "extracted-honey man," I shall always want to have a honey-extractor along when showing extracted honey at fairs. I also had two single-comb nuclei with glass sides, so arranged on posts as to be readily turned to look on either side for the queen. On top of each was a sign, "Bees and Queens," and it took only an instant for some of us to gather a crowd around these nuclei, and start off in a "speech," giving a little of the natural history of the queen, workers, drones, etc., and we frequently had listeners that were very much interested in what we told, and would ask questions, and sometimes kindly thank us for the information we gave. Dr. Tinker, Mr. Elias Cole, and C. E. Jones, also had nuclei for showing queens, but they were not so conveniently arranged, as they had to be held, and were liable to be tipped over and broken.

The description of the exhibit in our department would not be complete without mention of your "one-piece section" machinery. Unfortunately for our display, this, in order to have power with which to operate it, had to be put in Power Hall, fully sixty rods. I should think, from the Bee and Honey building. It consisted of four new ma-

chines, placed in a space of 12 x 15 feet. An abundance of the very nicest basswood blocks had been prepared (in Medina, I suppose), dressed to the right thickness, and cut to the right length for sections and placed in boxes that would hold 500 sections. These blocks were first run through the machine that automatically makes the openings in the sides; then over the "gang" of saws that cut the notches in the ends; then the sections were cut from the side by a saw that left them almost, if not quite, as smooth as if they had been sandpapered. From this machine they were put into one that cut the V grooves. It was a marvel of ingenuity and simplicity, and it was "just fun" to see it work. All the attention it seemed to require was to have a lot of sections, few or many, placed within its reach, and it would, without watching, cut the V groove just right in every section, and drop the sections all complete, in a box ready to be packed for customers. A great many were given away as samples, and a large quantity of price lists were here judiciously distributed.

I am not aware that such an exhibit of bees, honey, and the appliances of the apiary, was ever before made in this country. It was a continuous display for forty days (Sunday excluded), and our building almost became a home to some of us. It was the regular sleeping-place for two of your men, Uncle Aaron, and myself, and Uncle Aaron and I "boarded" ourselves. Uncle Aaron gained in health and weight every day, and got a "new lease of life," which to a Christian man worth scores of thousands of dollars, was of more value than money; but to me the blessing came with a loss of over two pounds a week in weight, and I never felt better in my life. The loss of flesh in my case I attribute to *worry*. The boys "nagged" me, and poked fun at me, and laughed at me at every crook and turn; and visitors were not in the least loth to do the same. There seemed to be no end to my "putting my foot into it" (you know what that means) at the most inopportune times, and once I came pretty near getting a "licking" by a Chicago man (not our friend Newman), who knew more about "manufactured honey" than we did. I believe I must tell you about it. Owing to my getting so badly scared I may not get it just exactly as it was, but it will be near enough for all practical purposes. When any of "our boys" found out any thing new, or got "sold," or came across a specially hard or green customer, or one that probably never kept bees, or else kept them in the old-fashioned way, and knew more about them than we did, they were sure to bring such parties to me. Well, one day a company of ladies and gentlemen from Chicago were visiting our "neck of the woods," and one of the men was telling about having bought and used manufactured honey there ten years ago, and that "it was just as good as the honey made by bees." After talking with him awhile, and finding he knew more than I did, I *very mildly* suggested that it wasn't just right to be telling such stuff, as that way of making honey was "played out" in Chicago, and referred him to friend Newman. He rather excitedly said that he guessed a man had a right to say what he had a mind too. With as little discretion as truth I admitted it, but, unfortunately, added, "A man has a *right* to *lie* if he wants to." Well, his looks and actions induced me to get up from the seat I was occupying, and put down a package

of honey I had in my hands, and for an instant I didn't know but somebody would get hurt. He rather excitedly asked me, "Did you tell me I lied?" Did you ever! But I was in a fix. I simply replied that he didn't ask that question in the right way. So he took it back and wanted to know what he *should* say, and I very kindly informed him that he should say, "Did I understand you to say that I lied?" He at once repeated my words, and I very innocently replied that I did not *know* how he understood me. My reply showed my guilelessness, and his own company joined in the general laugh, and tried to get him away; but he seemed to have a liking for "our boys," and I asked them to let him stay with us awhile, assuring them that we would not hurt him, and would not even let our bees sting him if we could prevent them. So they all, except my friend, went of laughing and we gave them a cordial invitation to come and see us again. This was the only time, I believe, when there was a cloud on our horizon.

A. B. MASON.

Auburndale, O.

Well, old friend, it is too bad, and it makes one feel sad to think that those boys should have been so naughty as to nag and worry you in the way you mention. I do not blame them for laughing, because almost every one laughs as soon as he gets acquainted with you, and I did not know before that a man could be found with cheek enough to get mad, even if you did intimate to him that he was not telling the truth. I suppose you gave him one of those cards with the thousand-dollar offer on it, and that he went away thoroughly satisfied and thoroughly converted. I suppose a great many people went away from that honey-exhibit a little wiser in regard to this matter of adulteration, and I am inclined to think that you are about the best man to undertake the great task of getting such a great stream of humanity to give up error and accept truth. Our work is not done yet; and I hope, doctor, that you are still using your big gifts among the people wherever you meet them.

PREVENTING AFTER-SWARMS.

A. E. MANUM'S METHOD.

HAVING noticed in GLEANINGS and other bee-periodicals, from time to time, various plans to prevent second swarms, all of which I have tried without satisfactory results, and having finally adopted a method of my own which is somewhat different from any I have ever seen in print, I will, with your permission, give it to your readers, that another drop may be added to the great fountain of knowledge from which a clear and invigorating stream is constantly flowing over the pages of GLEANINGS.

As stated above, I have tried various plans to prevent second swarms by hiving in different ways, such as moving the old hive to a new stand, and hiving the new swarm on the old stand; also setting the old hive on the new swarm or the new one over the old; also hiving the swarms by themselves, and giving them a portion of the brood from the parent hive, etc. All of these have proved to be unsatisfactory to me, owing to the fact that these methods have a tendency to lessen the amount of surplus, since the old hive is so reduced

that it is a long while before it becomes strong enough to work in the boxes. Hence we have only the new swarm to depend upon for a surplus, where we depend wholly upon clover and basswood for box honey. I always aim to keep every colony strong—the ones that have cast a swarm, as well as the new ones. My experience teaches me that light swarms during the honey season give no profit. I would rather have half a bushel of bees in one hive than divided by two, hiving a peck in each hive, when the honey season is at hand.

In hiving bees, the plan that suits me best is to return one-third of the swarm to the old hive, and hive the remaining two-thirds in a new hive, and add to it, as soon as may be, one or more two-thirds swarms (without queens this time), each time returning the third of the bees to the hive from which they came. The surplus queens, if good ones, may be returned to their respective hives after cutting out all the queen-cells. By this method the old hive is kept well stocked with bees, and work in the boxes is but little interrupted; the new colonies are made very strong, and are in the best of condition to store a large amount of honey in the boxes. As I do not desire a large increase of colonies, I strive to secure a large surplus, regardless of increase.

To prevent second swarms I go to the hive four days after a swarm has issued, lift out the combs one by one, and cut out all queen-cells but one, leaving the best one if I wish to rear a queen from this stock; if not, all are cut out, and a cell from some other is introduced. Then in four days more I again cut out any queen-cells that may have been started, after which there is no danger of more being started. Now, when the young queen hatches and finds no rival, and the bees not being able to rear another, owing to the age of the brood, the young queen is permitted to leave the hive for fertilization, without the bees following her; and in due time she will commence to lay. But if the young queen is allowed to hatch *before* the other cells are removed, as recommended by some writers, even if the cells are removed very soon after the queen hatches, there is danger of a second swarm. But if all surplus cells are removed *before* the queen hatches, there is no danger of a second swarm; at least, that has been my experience the past few years.

One night last season my son reported six second swarms that day (this being only his second season in having charge of an apiary, and he had forgotten my instructions of the year before); upon inquiry I learned that he had not removed the cells the second time; or on the eighth day, thinking that, if he removed them soon after the young hatched from the cell left in the hive when looking them over on the fourth day after the swarm had issued it would be as well. But the result was six after-swarms in one day. I visited his yard next day, and assisted him to cut out the surplus cells from all that had swarmed seven or eight days previously, and cautioned him to attend to this matter in the future, which he did, and the result was no more second swarms.

It may be asked, why I cut out the cells so soon as the fourth day. My answer is, that it sometimes happens that a swarm is retarded from coming out, for some days, owing to bad weather or some other cause. In such a case the young queen will hatch sooner than the eighth or ninth day; hence this

precaution. As second swarms are unprofitable to me, I aim to prevent their issue; and by close attention I find they can be prevented.

Bristol, Vt., Mar. 12, 1889.

A. E. MANUM.

BEE-CAVES, AGAIN.

THE DOOLITTLE PLAN A SUCCESS.

AFTER reading Doolittle's article on bee-caves, in GLEANINGS, I am constrained to give my experience. I wintered, or tried to winter, bees on summer stands for eight years, and the result was far from being satisfactory.

In the fall of 1886 I made me a cave 8x16 feet, and 5 feet deep at the caves, in the ground. I put in a 3-inch drain-tile 50 feet long. To a suitable frame of studding and rafters I nailed inch lumber. Above and around I banked 3 feet of dirt, and then sowed with sweet clover. I have compartments in the rear end, 8x12 feet, and 4x8 in the front, for vegetables. There are three doors, including the trap-door, and an ordinary ground floor inside. When winter comes to stay (that is generally about Christmas), I fill the hatchway with straw, and shut it up till spring. A 3-inch pipe passes up through the top.

In the fall of 1886 I put in 42 colonies of bees. In the spring I took out 42 in fine condition; and what surprised me most was that the cave was dripping wet. I dug a hole in one corner of the cave, and I think I took out ten barrels of water in 15 days, and I could not detect any trace of dysentery about a single colony. In the fall of 1887 I put in 52 colonies, and next spring I took out 50 in prime condition. This time two died—one of which was queenless, and the other one starved from neglect in the fall. This time the cave was as wet as before, and two nuclei showed some signs of dysentery, and some of the bees were in the cave for just six months, from Oct. 15th to April 15th. This winter has been so warm that I have not filled the hatchway yet, and the cave is dry. I am in the cave almost every day. The bees are wintering well. I am convinced that a good cave is the place to winter bees in this latitude.

WHEN WE MAY EXPECT A GOOD HONEY CROP.

I want to tell your readers when to expect a good honey season (and that next year is one in Iowa, at least). My observation has been, that always, after a plentiful rainfall, the next year will be a good honey year; and a poor honey season always follows a dry season; a wet season gives the trees and herbs a good growth of fibrous roots, and this is what gives us a good supply of nectar.

Newbern, Iowa, Jan. 22, 1889. WM. MALONE.

It seems a little singular that somebody else should have almost exactly the same idea you have in your concluding sentence. See the following:

ESTIMATING THE SEASON IN ADVANCE, IN THE LIGHT OF THE PAST; IS IT A CASE OF COUNTING CHICKENS BEFORE THEY ARE HATCHED?

Bees have wintered well to date, March 1st. I have 177 hives. I believe every one is all right.

Why can't some kind of correct estimate be given in advance as to what the honey crop will be for the season? For example, the season of 1889, according to indications, will give us a good crop. Why do I think so? I will explain. In this locality, during the fall of 1885 we had frequent rains; white

clover thrived everywhere. The fall pasturage was excellent. In 1886 we got a good crop of white-clover honey. The fall of 1886 was very dry. The grass and white clover burned out, even to the root. Hardly any white clover made an appearance in 1887. The fall of 1887 was dry, drier, driest, and I got no honey whatever in 1888 from white clover. The summer of 1888 was a fine one. White clover sprouted up luxuriously everywhere—little fine stuff, just from the seed. During the fall of that year the weather couldn't be better. The pasture was the very best for stock. Even now the white clover is green and in splendid condition to furnish us a crop of honey. Why is it this subject of a prospect of a honey-yield is never discussed, or is it too much like counting chickens before they are hatched?

A. N. DRAPER.

Upper Alton, Ill.

LARGE OR SMALL HIVES—WHICH?

A NUT FOR THE ADVOCATES OF SMALL BROOD-CHAMBERS TO CRACK.

SO much has been said in favor of small brood-chambers, I concluded to give them a trial. I commenced the experiment in July, 1886, putting 20 colonies, that season, on ten frames, said frames 6¼ inches deep, and same length as L. frames. During the summer of 1887 I put some 35 or 40 colonies more on these shallow frames. This divided my apiary about equally—half on ten L. combs, and the other half on the shallow frames. The season of 1887 was extremely dry and hot. The nectar from the flowers was, from the nature of the weather, of a very thick consistency—so much so that it required constant care on the part of the apiarist, in manipulating hives, to prevent the bees from robbing. Yet I secured nearly 6000 lbs. of honey from 98 colonies, spring count.

The season of 1888 was just the reverse of that of 1887, both as regards the nature of the weather and the nectar in the flowers. For six weeks during July and August, 1888, there was very little disposition on the part of the bees to rob. But I obtained only 4500 lbs. of honey from 108 colonies, spring count.

Now for the results from the different sizes of brood-chambers. In 1887 there was but little difference, and that was in favor of the large hives. In 1888 the large hives not only gave me nearly three-fourths of the surplus obtained, but had an abundance for winter stores, while the small hives were quite light when placed in the cellar, and will have to be fed early in spring to carry them through.

I have for several years entertained a theory in regard to storing and evaporating the moisture from honey, and this theory is substantiated by the past two years' experience.

The statement that *all* the honey goes into the surplus receptacles when small brood-chambers are used is quite true, as there is no other place for it. But it is my opinion, that few if any of the advocates of small brood-chambers know how much they lose by not having sufficient room for storage and evaporation of nectar, especially when, from the nature of the weather, the nectar is very thin, as is often the case in wet seasons. Notwithstanding the many plausible arguments presented by able writers in favor of small brood-chambers, I

would not give my past two years' experience for whole volumes of such arguments. What would you think of the man who would set to work to produce 500 gallons of syrup per day, with an evaporating capacity of only 250 gallons per day? Somewhat ridiculous, is it not? Yet this is about the condition of affairs when put to the actual test.

Liverpool, Ill., Feb. 12, 1889.

S. A. SHUCK.

FUNCTION OF SALIVA.

PROF. COOK REPLIES.

I HAVE found no time before this to reply to the kind criticism of Mr. S. Corneil, in GLEANINGS, 1888, p. 931. I did say, in my first criticism of Cheshire's first volume, that the author's statement, that the "principal function of our saliva is to change starch into sugar, is a strange error." I am still of that opinion. I do not believe that any real experimental physiologist will disagree with me. I regret if my assertion in commenting upon Mr. Stachelhausen, that "we secrete saliva almost wholly to moisten our food," makes me appear *morbidly* sensitive. I really am not so. I am sensitive regarding what I deem erroneous. I have no feeling whatever in this matter, nor do I believe Mr. Corneil has, other than that the truth should prevail. If I said that Mr. Cheshire stated that the sole use of saliva was to digest, I certainly quoted from memory. He says its principal function is to chemically change some parts of our food, and notably starch. Again, I say, "Most English authors, and Foster with the rest, argue that saliva may do a great part of the work." Mr. Corneil adds, "What Foster does say is this: 'Its characteristic property is that of changing starch into sugar'—no arguing that it may do in this statement." Now let me quote Foster, page 184: "The chief purpose served by the saliva in digestion is to moisten the food, and to assist in mastication and deglutition." *This is its chief purpose.* That its characteristic property is to convert starch into sugar, is true. There is scarcely a better test for saliva. That is why I said, "That saliva will change hydrated or cooked starch into sugar, no one doubts." Now, Mr. Editor, let me briefly add what I believe to be just the truth in the case—what I have taught my students for years, not because I have read it in books, but because I have actually proved it, as do my students, and as Mr. Corneil can with no very great trouble or pains. Saliva of man, the pig, rabbit, guinea-pig, and the rat, is amylolytic; that is, it will digest starch, though far less actively, than does pancreatic juice. The same thing is very feebly true of the saliva of the cat, or horse, and sheep, while that of the dog is not so at all. But this is true of no saliva, except in an alkaline liquid. Thus, if we take cooked starch—only cooked or hydrated starch is acted on by any saliva—and simply put it into the mouth for a moment, a trace of sugar will appear. If, then, starch should remain in the mouth, and be mixed for some time with saliva, it would largely, perhaps wholly, change to sugar; but it stops only to be moistened, and is rushed forward to the stomach, where it is mixed with the acid gastric juice, and then the saliva is entirely powerless to digest the starch further. It did commence, but stopped before it had more than just begun. But when the starch reaches the

small intestine, and is mixed with the far more amylolytic pancreatic juice, it is speedily changed to sugar, or, in other words, digested. Now for the proofs:

First, only cooked starch is ever digested by saliva. The tropical man, then, who eats his starch raw, must depend wholly on other ferments for this digestion.

Second, feed a rabbit cooked starch. While we find a trace of sugar in the mouth, as we do in our own case, we find no more, only a mere trace, in the stomach. We see that, while the saliva has this property, it does not have this function. It can do it in an alkaline liquid—it can't in an acid one, like the juices of the stomach.

Third, while our saliva in the mouth will digest starch, and does very slightly, it will not do this if in a test-tube we add hydrochloric acid—the acid that makes the juices of the stomach acid; so we know that this change is at once cut short as the food enters the stomach.

Fourth, one element of the pancreatic juice does this work much more energetically than does the saliva, even in the mouth, and so there is no call for such action from the saliva, which is simply to moisten or soften the food, as Bernard's classic experiments showed years ago.

Fifth, the horse and cow eat much starch, and their saliva can't do this work. If the pancreatic juice does this for them, it would be logical to suppose that it does the same for all animals, especially as direct experiment proves that it can and does.

Sixth, the salivary glands and the saliva are as marked in dogs, cattle, horses, etc., as in man; but in these animals we know it does not digest starch. This, then, shows that the saliva has a separate function, which we know to be to soften the food.

I have made many experiments in this field, and have no doubt of the correctness of this position. I have suggested how others may prove the truth of it, as Fehling's test for sugar is simple, and easily applied.

We see that this matter in physiology is of practical importance. We must eat slowly, that the saliva may be thoroughly mixed with the food, and the food well cut up, else it will be impossible to digest the food properly when it arrives in the stomach and intestines. Bolting our food is not hygienic.

Agricultural College, Mich.

A. J. COOK.

HEART'S-EASE HONEY.

HOW IT GRADES WITH OTHER HONEY IN THE MARKET.

A SUBSCRIBER OF GLEANINGS writes me as follows: "Please tell through GLEANINGS how heart's-ease honey grades in Chicago, as compared with white clover, linden, etc. It is considered A 1 here among farmers. . . . Do you think I could do as well with the extractor? Do you think extracted as profitable as comb? Also, what do commission men generally charge per pound? Three short crops can be secured here in one season—first, white clover; second, basswood (by moving bees 3½ miles); third, heart's-ease."

The honey gathered from heart's-ease is not as light-colored as that from white clover or linden, and has a somewhat stronger flavor. A well-ripened article, though, when granulated, looks almost as white as clover. It granulates in very fine crys-

tals, forming a smooth, even grain, perfectly dry, but not quite as hard as a good article of clover. Let me remark, in passing, that I do not consider any honey first-class unless it will candy so as to be hard and perfectly dry.

The comb made from heart's-ease is as white and delicate as any made. In most of our markets I believe it is usually graded and sold as white clover. With many dealers, all comb honey that is nice and white is white clover, while all that appears dark is buckwheat. This, to some extent, is true of extracted honey. Nearly all honey produced is from sources more or less mixed, according to the season and locality in which it was gathered. If you ask any large dealer in honey for samples of white clover you may get several different flavors, none of which you will recognize as the white clover of your locality. This being the case, there is a tendency among dealers to class all honey, that is reasonably light in color and mild in flavor, as white clover. A friend of whom I bought some honey almost entirely of heart's-ease, writes that a well-known Chicago dealer said of some more of the same lot, "It seems to be almost entirely white clover."

Tastes differ as to quality. Some do not like the flavor, others prefer it to any other variety, while some never learn to distinguish any difference between it and other kinds. A bee-keeper of some years' experience admitted to me not long ago that the only kind of honey she could positively distinguish by the flavor was that from sweet clover.

Heart's-ease honey has one serious fault. It is injured more easily, and to a greater extent, by overheating than any other kind I am acquainted with. The heat of boiling water, if the whole mass is heated up to that point, will utterly ruin it, giving it a flavor and odor that reminds me of an infusion of hay. Unless consumers are made aware of this fact, unpleasant results may follow. It will be seen that it is not fit for cooking purposes, as the "hay tea" flavor is not generally liked. The nectar from heart's-ease seems thicker than that from most plants. This was particularly the case last season, when it seemed ready to cap over almost as soon as it was brought in. On this account I do not think it as profitable in the extracted form as in comb.

As to the relative profit of producing comb or extracted honey, I would refer my correspondent to my article on the subject on page 691 of GLEANINGS for 1887. No one can be certain, until he tries it, which will pay him best; but in the majority of cases, comb honey will be found more profitable. With regard to the rest of the letter, commission men generally charge 5 per cent on sales, though in some places 10 per cent is charged. If my correspondent makes a success of moving his bees, especially for the basswood flow, I hope he will report on it. We do not know nearly as much on the subject as we ought to. I believe it is destined to play an important part in the bee-keeping of the future.

HONEY IN PAPER PACKAGES.

You will remember the article I wrote on small paper packages for extracted honey. I send you some of these by this mail. The honey is not very good in quality, being a mixture of various sorts, and the paper in which it is wrapped is simply GLEANINGS paper. I hope it will reach you without damage. It seems to me that something might

be done in this way to furnish a market for a great deal of honey.

J. A. GREEN.

Dayton, Ill., Mar. 9, 1889.

The candied honey in little packages looks very pretty, only it is somewhat sticky. This may be remedied, however, by wrapping it up in paraffine paper, exactly as we get caramels from the confectioner's. I presume a very choice grade of honey would sell well as confectionery, but it would be considerable trouble and expense to put it up in these packages; and if a trade is once started it will be greatly crippled or perhaps killed by using an inferior article. If I am correct, some honey candies in a good deal better shape than others. Small packages, say one inch square or less, would probably keep their shape, and be neat to handle. If not sold immediately, however, I am a little afraid that it would look old and uninviting.

MANIPULATING CHAFF HIVES, AND PREVENTING SECOND SWARMS.

GEO. E. HILTON GIVES A FEW FACTS IN FAVOR OF CHAFF AROUND THE BROOD-NEST.

THE great bugbear held up against chaff hives is their weight in manipulation. Having always used chaff hives I have learned it is unnecessary to move them after they are once placed upon their stands, which (i. e., the stands) should be substantial. For this purpose I like a rim made of 2 x 4 oak, or some timber that does not rot easily. When the chaff hives are once on their stands they certainly possess advantages that the single-walled hives do not. Bees will certainly build up faster upon less stores in the spring, and are less liable to spring dwindling. When the heat of summer comes on, your surplus receptacles are better protected from the scorching sun without the use of shade-boards; the brood-nest is more comfortable, and when bees in single-walled hives are lying out and doing nothing for fear of melting their combs, bees in chaff hives are busily at work; and I have yet to have the first comb break down in them.

In manipulating the surplus there is less stooping, and, as a consequence, less backache; and with both kinds in the yard for the past ten years, I have received enough more honey from the chaff hive to pay for their extra cost. They are always ready for winter by simply putting on a chaff cushion when you remove your surplus crates in the fall. There is less swarming than in the single-walled hives, for the same reason that they work when those in the single-walled hives do not. They are more successfully handled against second swarming. When a swarm issues I lift off the surplus cases and set them on top of the next hive, lift off 7 of the 8 frames, and place them with the adhering bees in an empty hive. I then put in seven frames of foundation (in the parent hive), replace my surplus cases, and by this time the swarm has clustered. I next shake what I can of the swarm into my hiving-basket, invariably getting the queen the first time, and then dump them upon the alighting-board, and the work is done. As the remaining bees will soon return to the parent hive, and all the field bees giving you the same working force as before, with energies redoubled, look out for your surplus room, for the queen will occupy

the foundation as fast as drawn. Your seven frames are so depleted (with yet enough bees to care for the brood) that they will not swarm one time in ten, and your honey will all come from the parent hive, and you will have fewer unfinished sections, unless you get a fall flow, as we did the past season when I had to extract the brood-nests to give the young queens room to lay. In my locality I save all the first swarms up to Aug. 1, and have never yet failed to have them in good condition for winter.

When I read of some of the methods used in manipulating the single-walled hives in securing honey, and in the prevention of second swarms, I fear that I should need a book-keeper to keep things straight. With me it is all done at one operation, and I have no further thoughts in the matter. It is a success, both in the production of honey and the prevention of second swarms.

Fremont, Mich.

GEO. E. HILTON.

Why, friend H., it seems to me a little funny to have you indorse the chaff hive in the vehement way in which you do. Your ideas are mine exactly when I invented our present method of making chaff hives; and my experience in all these years agrees exactly with yours. Now, it seems to me that those who have been so vehement—yes, and I might almost say *bitter*—in denouncing the chaff hive should remember there are quite a few who think just as you and I do. Some have objected to the chaff hive because it is inconvenient for handling the combs; and it surprised me when I heard it, for I find the chaff hive the most convenient, even for queen-rearing, of any hive I ever had any thing to do with; and it is because I can lean against it when handling the combs, and support myself without pushing it over or off its foundation. When working with the Simplicity hives I am obliged to lean over the hive and work in a leaning position, without any thing to support me; and I have always found that, when I go from a Simplicity hive to a chaff hive, especially when I am tired, that the chaff hive rests me just because I can lean my whole weight against it while I lift out the combs; and I want the old-fashioned two-story chaff hive, just as I first made it. In your method of working you do not say what you do with the combs and adhering bees that you lifted out; but I suppose they are taken away to make another colony. We have not found this very good economy unless we get some working bees from some other new swarm to put with them; otherwise there will not be any pollen or honey brought from the fields for nearly a week.

THWARTING ROBBERS.

ALSO SOMETHING ABOUT THE SIZE OF THE BROOD-CHAMBER.

LAST August I received a letter from H. L. Jeffrey, of New Milford, Conn., in which he said, "I must send you a trick that I have tried many times at this season of the year, or I should say this time of honey-dearth. Several years ago I was handling a stock that was being robbed. The bottom-board of the hive projected about 4 or 5 inches in front. The stock was

quite demoralized, and were all over the ground, and the robbers were going in and coming out like mad demons. I looked at them for a moment, then around, and, seeing some sticks half an inch thick, and a shingle about 6 inches wide that had been used over the combs the previous winter, I just put the half-inch sticks at each end of the alighting-board, then the shingle on top, and pushed it tight to the front of the hive; and, wasn't it fun to see those robbers try to go through the front of the hive? the robbers inside coming out from under the shingle, and unable to find their way back, and at the same time the demoralized bees belonging to the hive were quietly crawling back and leisurely walking under the shingle, as cool as though enjoying the sight of the acrobatic exercise their defeated plunderers were taking."

Mr. Jeffrey found the plan to work equally well in subsequent trials. I was so unfortunate (or, rather, so fortunate) as to have no case of robbing last season after getting his letter; but from the well-known habits of bees, I think the plan well worth trying, even if Mr. Jeffrey's long experience did not give me confidence in his decision. The whole affair is very simple. The entrance from the outside is closed, and a new entrance made, while the exit remains practically unchanged. The robbers remain, frantically attempting to force an entrance at the one spot, while the bees belonging to the hive are more inclined to hunt for another entrance.

HIVE FOR COMB HONEY.

A correspondent writes: "Please answer through GLEANINGS what size of frame, size of super inside, and size of hive inside, also how many frames to hive, and what size of section you would use if you were going to adopt a hive for comb honey. Would you want it larger for extracted honey if two stories are used?"

The frame I am now using and have been using for a good many years is 18 x 9. I do not know that any different size would give better results, although it must be remembered that for a long time I have used no other size, and am likely to be prejudiced. I would not adopt that size, however, if I were beginning anew, for the simple reason that I don't want a size different from every one's else, unless there is strong reason for it. The size of the Simplicity-Langstroth frame is only $\frac{1}{8}$ inch shorter and $\frac{1}{2}$ inch deeper—so nearly the same that, for practical purposes, there is no difference, and so I should prefer that which is used by many others, instead of having an odd size. I think I should prefer a hive to take eight of these frames, thus making a hive 18 inches long and 11 $\frac{1}{2}$ inches wide, inside measure. I would use the common 1-lb. section, 4 $\frac{1}{4}$ x 4 $\frac{1}{4}$, to go in a T super measuring inside 17 $\frac{3}{8}$ x 12 $\frac{1}{8}$ x 4 $\frac{3}{8}$.

I am not authority on extracted honey, but I do not think I would have a different size of hive, if I expected to use some hives for comb and some for extracted. If, however, I intended to raise no comb honey, but extracted altogether, I should do some pretty heavy studying or experimenting to see if a ten-frame hive might not be best.

Marengo, Ill.

C. C. MILLER.

The idea of a shingle or other thin board, supported on narrow strips over the entrance, is quite old, and a pane of glass in place of the shingle seems to answer still better. If robbers are acting very bad, the

shingle would have to be fastened down with small nails; but an ordinary pane of glass has weight enough to keep its place. I think that prevention in case of robbing is much better than cure; but after they do get to going, the idea is often valuable. It is my opinion that such cases of robbing have more to do with bees being voted a nuisance in a neighborhood than any other one thing.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

EARLY HATCHING.

MY bees are situated on a western exposure of a hill. March 17th they carried in the first natural pollen that we could see. One colony was not carrying pollen. Concluding that that colony was queenless, I opened the hive and found neither brood, larvæ, nor eggs. I then searched for the queen, and found a young one, white as a corpse, certainly not five minutes old. I pushed aside the little cluster of bees where she was, and found two capped queen-cells, and one with its "coffee-pot lid" open where the young queen had just come out. I watched her a few minutes, when she dipped her nose into a cell and started out over the comb. About the queen-cells I found two or three cells of capped brood. Apparently the old queen had just lived until about March 1st, then laid six or seven eggs, and died. As there are no drones flying, and the weather is very bad, I think the chances are against this queen being fertilized, and I shall lose the colony, as it is too weak to raise a new queen from eggs in April. At least, I fear it is too weak to raise good queens. think St. Patrick's Day in the afternoon is rather early for young queens in this latitude.

PHILO S. DILWORTH.

Bonney, Pa., March 21, 1889.

SORGHUM MOLASSES TO FEED BEES IN SPRING.

Please tell me whether sorghum molasses or syrup is fit to feed bees in the spring. Of course, I know it would be unsafe to give it in the fall for winter supplies, but I thought it might be good in the spring to feed up to stimulate queens, etc.

Worthington, Ind., Feb. 5, 1889. J. A. MINICH.

Sorghum molasses will do for spring feeding whenever the bees fly freely; that is, providing the bees will pay any attention to it. Unless the quality of the sorghum is quite good, and no honey of any sort is to be had in the fields, bees will seldom work on it. During a drouth in the fall, when we are keeping nuclei going for the purpose of raising queens, sorghum molasses will often answer a very good purpose. It is so distasteful to bees that they seldom care enough for it to start robbing, and in this respect it is much better than honey.

THE NON-REVERSING EXTRACTOR, AND WHAT MR. COWAN SAYS ABOUT IT.

We take pleasure in making the following extract from a private letter received from our brother-editor, Mr. Thos. Wm. Cowan, of the *British Bee Journal*, relative to the non-reversing extractor mentioned and described on pages 683 and 773 for 1888:

I was interested in your taking up the honey-extractor to extract from both sides at one operation. I have been looking forward to remarks from others. The diagram of one you have made is very nearly exactly the same as the one I made and used, and was described in the *British Bee Journal*. If you like I will send you the extract referring to it. The reason I gave it up at that time was because the combs got damaged unless great care was taken, and it was not safe to put it into the hands of careless people. You know we did not have wired frames, and new combs heavy with honey used to become crushed up toward the top-bar, which was on the outside circle, and toward which the centrifugal force pressed them. With old combs, such a thing would not happen. Otherwise the honey was extracted without any difficulty. This extractor is still in existence, and is in the collection of appliances I presented to the British Beekeepers' Association.

THOS. WM. COWAN.

Boulevard Grancy, Lausanne, Switz., Dec. 22, 1888.

ARE BLACKS MORE HARDY THAN ITALIANS?

Which are the best bees to winter, in your opinion? My gray bees are wintering all right. The hives are just full of bees, but the Italians are all dying. A week ago to-day my bees had a good fly, and the Italians would crawl out and get a chill and die.

Deshler, O., Feb. 23, 1889.

T. OBERHITNER.

As a rule, blacks are not more hardy than Italians. The two races of bees, however, are so different in their habits that it is not unfrequent to find one wintering better than the other. For instance, while the blacks are working on buckwheat, the Italians will often be working on red clover; and in this case the difference in the kind of stores might make a difference in wintering. Italians will also sometimes work on honey-dew while the blacks will not, and I should think likely that that is the trouble in your case. Warm weather, that will enable the Italians to fly, will probably fetch them up all right.

HOW TO MAKE A START IN BEE-KEEPING.

I want to get started in the bee-business again, on a very small scale. A number of years ago I bought your A B C and got two hives of bees; but the bees and my bright hopes, one by one, took flight and left me "weeping sad and lonely." There are only black bees around here, and the owners ask \$7.00 per hive for them. But I have not that much to throw away, as my John says. We have all kinds of fruit, large and small, which our neighbors' bees thrive on from the first cherry blossom in May till the last raspberry in August. If I must gather bees by the handful while picking raspberries, I am quite sure that I could do it with greater equanimity if I knew that some of them were my own. Your advice in the A B C is to get two or three pounds of black bees and a fertilized Italian queen. Is that still your advice? If so, I can get the black bees here.

MRS. C. H. TARBELL.

Bedford, N. H., Mar. 12, 1889.

Yes, my friend, that is still our advice. Almost everybody can get bees of some sort near home; and all you have to do is to get such a queen as you want, by mail; and queens are carried by mail safer and quicker than hives of bees, even by express.

WASTE FELT VS. CHAFF, FOR PACKING.

Friend Root:—I want to talk to you a little more in reference to the sample of packing I sent you, in hopes it may be of some benefit to some bee-keeper in this vicinity and other places where fur-hat factories are easily accessible. You reply, the great objection to it is the expense, and on that account you prefer chaff, especially wheat chaff. In this locality we can't get wheat chaff, as comparatively no wheat is raised in this vicinity, and the best chaff we can procure is oat chaff, which I have always used until the last one or two seasons. But after using this waste—like sample sent you—I think it much superior; and the only objection I have to it is, that the fur and hair stick to the clothes, and it is quite a bother to get it off. As far as the expense is concerned, it costs no more than chaff. It is the waste from the shaving machine, use in the manufacture of fur hats, and is composed of fur and hair. Now, if any bee-keeper in the vicinity of a fur-hat factory will go to the factory and get this waste to pack his bees in, I am sure he would decide with me that it far excels chaff. It costs nothing. The manufacturers are generally glad to have it taken away.

S. H. HICKOK.

Bethel, Conn., Feb. 9, 1889.

We have no doubt, friend H., but that the waste from hat-factories will answer as well as chaff; but the great objection to it is, that there are very few bee-keepers indeed who are so situated as you are, to get this kind of packing; and the number of bee-keepers who can *not* get some sort of chaff is comparatively small.

THE WORK OF MICE IN THE HIVES.

I went into the winter with 16 colonies, after uniting and giving, as I supposed, plenty of stores to carry them through; but I find I am taken right back where I was one year ago, as I have nine colonies left to date, all very strong and fair. We are told in the A B C that mice are enemies of bees. We try to guard against them, but mice had been in no less than five colonies of the 7 lost—the first time that a mouse ever got into a colony of my bees. You see, the entrances get large by the action of the weather, and the passing of the bees in and out. That thing will never occur again with me; however, I think on the whole more stores have been required to bring bees thus far than any other winter since I have had bees.

Hinckley, O., Mar. 15, 1889.

A. A. WEBBER.

THE WARNER PARALLEL GAUGE; QUESTIONS CONCERNING IT.

Are the rods or screws of Warner's improvement to saw-tables, for regulating the gauge, long enough so that the gauge can be set as much as two feet from the saw with a gauge $3\frac{1}{2}$ inches wide, or how long are they? I often use the parallel gauge to cut off with, and want to cut my bottom-boards two feet long; does this attachment still work well? Do you still sell them, and at what price?

Le Sueur Center, Minn.

R. KENDALL.

Friend K., the screws in the Warner parallel gauge, such as we send out, are 26 inches long. The gauge itself can be set 24 inches from the saw; but if so arranged it will not come near enough to saw sections, brood-frames, or other thin stuff, without putting a straight piece of plank of suitable width on the face side of the gauge. On our

regular section saw-tables, such as we use in our factory, the screws are shorter. When so arranged, the gauge can come in contact with the saw itself, if necessary, or be set back 22 inches. The Warner parallel bar and screw attachment is the best arrangement of the kind we have ever used. A few quick jerks of the chain will cause the gauge to be set at any point. One of its chief merits is, that it can be adjusted to a hair's breadth, if not *exactly* at the point desired. With the old parallel gauge it was very difficult to get an exact adjustment. We use these screw gauges in our factory exclusively now. We sell them with screw, chain, and every thing complete, for \$5.00.

TO INCREASE THE SIZE OF WORKERS BY INCREASED SIZE OF CELLS NOT A SUCCESS.

Some time since there was a good deal of discussion as to whether we could not increase the size of worker bees by making comb foundation a little larger than the regular size. Last spring in looking over my hives I found in one of them that had a good deal of drone comb a queen (I have had them before that would not lay a drone egg nor make any preparations to swarm during the swarming season) that had not laid a drone egg; but being pressed for room she had filled three drone combs with worker brood—no mistake; 30 years in handling bees has made me familiar with the difference between a worker and a drone. Those workers were no larger for being raised in drone-cells.

HOW TO MAKE SMOKER-LIGHTERS.

A great convenience in the apiary, is rolling up paper balls the size of marbles, putting about an inch of oil in, in a quart can, filling it up with the paper marbles, and you have the best and quickest lighters for your smokers that you can possibly have; by making them the size of a large egg, you have a good one for the kitchen stove. A Mr. Wilson said to me a few days ago that you can clean your smoker of soot very easily if you put some salt on the fire which you make to clean it.

Los Gatos, Cal.

S. S. BUTLER.

You are right about the matter of enlarging bees by giving them larger cells. Facts similar to those you have given have been sent in repeatedly; but for all that, every little while somebody invents over again the idea of enlarging the cells.

EXCLUSIVE TERRITORY. OVERSTOCKING, AND WHO IS TO BLAME FOR IT?

I fear my article on "exclusive territory" is not quite understood by the readers of GLEANINGS. Numerous propositions have been made from time to time by different people to secure exclusive territory by legislation. I was bitterly opposed to any law that would work injustice to the poor, therefore I wrote my article on "exclusive territory." I said the only fair way to secure such rights was by purchase, rather than by legislation. I do not believe in monopoly of any kind, where it will operate against the poor, not even patent bee-hives. Personally I have no faith in the feasibility or advisability of exclusive territory. I think it would be cheaper to move to a location where there are not so many bees than to try to buy out the neighborhood. Bee-keepers are themselves much to blame for the overstocking of some locations. A man gets a new variety of chickens, and he makes

haste to sell hatching eggs to all his neighbors at "two dollars a sitting." Before he is well aware of it he finds everybody crowded with that kind of chickens and he himself trying to trade his fine eggs at nine cents a dozen to the village grocer for molasses and stale cheese. Just so in the bee-business. A man gets a few bees, and hastens to advertise "Bees and Queens for Sale." He discounts his future profits for present benefits, and shortly finds all his neighbors in the bee-business, the locality overstocked, and his honey begging for a market.

PHILO S. DILWORTH.

Pittsburgh, Pa., March 5, 1889.

I also am opposed to any monopoly that works injustice to the poor, and I also believe that the way to secure exclusive territory is to make a contract with your neighbors not to keep bees if you can do so; and I still think that, in many neighborhoods, this can be accomplished. If we are going to raise forage for bees, and have a honey-farm, it would be of the utmost importance that the adjoining farms should agree not to keep bees. Why can't it be managed as well as they manage the matter of making leases when drilling for gas and oil? Before men go to the expense of sinking a well, they very carefully lease the land adjoining, so as to have the control of the locality in case it should be found to be a valuable one. Now, while it is true that the man who gets a new kind of poultry may stock the neighborhood until he runs the price down, I think great good comes from this kind of work, many times, without getting the price down, or, if you choose, *before* the price gets down. Surely it is better to buy choice stock of any kind of your neighbors than to send away off to a distance, pay heavy express charges, and then get something you have not seen before handing over your money. In the same way I believe it pays most bee-keepers to advertise bees and queens for sale. Now, none of you need accuse me of saying the above from selfish interests, because I have just advised very strongly trading with your neighbors instead of sending away off to a distance; and I do think that bees and queens had very much better be bought near your own home, than to send away off, take the risks of heavy charges, damage in transportation, and may be getting foul brood besides. When it is impossible to get what you really need, in your own neighborhood, why, then, of course, you can call in the aid of the express and freight companies.

HOUSE-FLIES, AGAIN.

A subscriber from Ohio says he finds myriads of flies in his horse manure in winter. He says that, as the eggs were laid last summer, drawing the manure out in winter would freeze out the insects. This is not true. The house-fly hibernates in winter—this is genuine hibernation; so eggs will be laid next spring. This explains why flies are scarce in early spring and summer. They breed rapidly, and become very numerous by fall. The same subscriber says: A neighbor drew out all his manure in winter. Soon his manure heap was full of house-flies, yet all was made in the last two weeks. An explanation is asked for. I answer, there is some mistake. House-flies do not breed in

winter, and all insects come from eggs; thus if flies were seen they came from eggs laid last autumn. Hence either the manure was not drawn out clean, or else some old manure, or rubbish with eggs, was thrown out with the manure. Flies do not lay eggs in winter, in the North. All insects come from eggs. Any observations that seem to contradict these statements need to be repeated.

Agricultural College, Mich.

A. J. COOK.

I think your explanation is correct, friend Cook. When our friend wrote me, it did not occur to me that the eggs laid by flies might remain several weeks or months, until the temperature was right. If this is so, it will account for the presence of larvæ in the manure, which I presume has been observed by many, even during the winter time.

THAT QUEEN OF MRS. CHADDOCK'S UNDER A GOBLET; DOES A SWARM EVER ABSCOND WITHOUT THE QUEEN?

Friend Root:—I think Mabala B. Chaddock owes a word of explanation in regard to what she says on page 89 about 4 swarms of bees going to the woods, and leaving their queens under a goblet on a plate. Now, does she mean that those bees went off without any queen, and set up housekeeping in the woods, without any queen? If she does, then she has "downed" Langstroth, Quinby, and A. I. Root as effectually as she did A. J. Cook in regard to the color and scent of flowers. These fathers of apiculture have taught the young American that no swarm of bees will leave without the queen, and my experience has proved the correctness of their theory. Now, if sister C. has made the discovery that a swarm of bees will abscond without a queen, what is the use of clipping the wing to prevent absconding? or did the bees know that the queen's wing was not clipped, and the good woman of the house had her under a glass goblet, and that she would let her go in a few days, and that she would follow them to their new home, and by that time they would have house-cleaning done ready to receive her ladyship?

The way I keep the bees from putting propolis in the beveled joints is not to have any beveled joints, but use a hive with square joints, like the old-style Heddon hive, thereby obviating the use of tallow, chisel, and hatchet; but if I had bevel-joint hives to sell I might recommend the use of tallow and oil to prevent the bees from gluing them together.

Sherman, Ill., Feb. 6, 1889.

D. D. COPER.

Friend C., we *did* not understand Mrs. Chaddock to say that four swarms went off to the woods, leaving their queens under a goblet. No doubt one of the queens was under the goblet; but the other three ought to answer for even four swarms—that is, if they went to the woods *en masse*. Mrs. Chaddock did not make her point very clear about the four swarms that went to the woods.—Your last sentence, it seems to me, makes out that you are a "badder man" than bee-keepers in general. I know there are some men who would sell a thing that they knew was worthless, and a hindrance to their fellows, if they could make money by it. Surely there are not many such among the readers of GLEANINGS; and I do not believe there are many who believe the *editor* would set the example. We furnish

any kind of hive that anybody wants; and we sometimes make Simplicity hives with square joints instead of beveled ones, where the brethren think they prefer them that way. But 100 of our customers prefer them with the bevels, where one asks to have them square. Bee-hives without the bevels were the rule before the Simplicity was invented, and they are to be found even yet, more or less, in almost every apiary. Langstroth, you will remember, adopted the plan of having the upper story slip over the lower one in order to keep out the wind and rain, and to keep the upper story in its place. I thought this took too much lumber, and, besides, I objected to hives with projections. When I used Langstroth hives exclusively, I could get only three hives of bees into my one-horse wagon. The portico stuck out in the way, the rim around the outer edges stuck out in the way, the upper story stuck out in the way, and the covers also stuck out in the way, and got bumped loose, letting the bees out to sting my horse. After I invented the Simplicity I could set eight hives of bees in my one-horse wagon and take them to a buckwheat field, without the top stories slipping off from the lower ones, or the covers getting slipped off or bumped off. When I wanted to pile my empty hives up under shelter, the Simplicity ties could be placed one on top of the other, covers, bottom-boards, and all, clear up to the ceiling. The next tier would go up tight against it, so that it was very much like putting the hives in the wagon. A certain size of room that would hold only eight or ten Langstroth hives would hold twenty or thirty Simplicitys. Now, if anybody wants to go back to the old style—if they want hives without the bevels, or even if they want box hives, we shall be glad to serve them.

DOES WILLOW PRODUCE HONEY?

I have ten colonies of bees in chaff hives of my own make. One colony made 96 lbs. of comb honey last summer. I should like to know for certain whether yellow willow produces honey. I have watched the bees at work on them, but never saw them get any pollen. I think this is conclusive evidence they get honey; and by the way they worked I think they were getting it in pretty large quantities. Would it pay those living by streams of water to set out some branches? They would save the banks, and give the bees work.

W. A. WILLIAMSON.

Friendly, W. Va., Feb. 11, 1889.

Your evidence seems pretty clear, friend W., that bees do get honey from the willow. In our vicinity, willow hedges were put out, perhaps 25 years ago, to a considerable extent. During favorable seasons bees do sometimes work considerably on these willows; but as a rule I think they amount to but little. Perhaps this is because they are not of the variety that yields honey most.

BEEES IN TOWN.

I have been taking GLEANINGS for three years. I can hardly do without it. I am a beginner with bees. I had good luck with them, but did not get much honey last year, on account of dry weather. I put away 28 colonies in winter quarters, under a

shed, and filled in with sawdust. The weather has been very warm here. We have had no cold weather as yet. I live in a town of about 30,000 inhabitants.

B. M. HUBLE.

Wallaceburg, Ont., Can.

Bees do very well in town; in fact, a great many bee-keepers have their colonies inside of the corporation limits. Occasionally there is trouble with neighbors; but usually it is a case of ill will from other causes. Most of such troubles can be avoided by occasionally presenting your neighbor with a nice sample of honey.

REPORTS ENCOURAGING.

ENCOURAGING FROM A. E. MANUM.

BEEES in this section of the State are, we think, wintering nicely, as the winter has been very mild for this climate. They had a very fine clearing flight on Jan. 17th and 18th, and also March 5th and 6th. On the 6th I opened a few hives and found, to my great delight, that but very little of their stores had been consumed, and the bees appeared to be in a healthy condition, with but a few dead bees on the bottom-board. We are very hopeful that this coming season will prove to be one of our old-time honey seasons, as clover made a very fine growth last fall, also the bass-woods made an excellent growth of new wood during last summer, which indicates a full bloom the coming season.

A. E. MANUM.

Bristol, Vt., Mar. 14, 1889.

55 GALLONS OF CHUNK HONEY FROM 11 COLONIES.

I bought a place in this county, and moved to it in the fall of 1887, and with the place I got a few hives (9, I believe) of hybrid bees, in a bad condition, "robbed almost to death," including the spring swarms. After the last winter "starve outs" I have 11 hives, mostly Simplicity. I did not have time to work with them much, nor the foundation to straighten their combs; and having sold my extractor before moving, I decided to "let 'em rip." I did not weigh the honey, but the vessel's capacity that it filled was 55 gallons, "chunk honey," as the A B C would call it. My bees went into winter with plenty of stores, and are now rearing brood very nicely.

W. M. WOOLSEY.

Floresville, Tex., Mar. 2, 1889.

LARGE VERSUS SMALL HIVES; \$1600 AS THE CASH PRODUCT FOR ONE SEASON.

I have 260 colonies, in hives containing 800 inches of comb surface. I use two of them for a hive, and have managed for the last eight years on exactly the plan that Dr. Tinker generously offered to give free to the bee-keepers, in the *American Bee Journal* lately. I like the plan, and secured seven tons of comb honey by it this poor year. I cashed it long ago for \$1600. I know that, with the hives and system I now use, the best results are reached with one-half the work in summer management, as compared with the common hives and system. I am wintering 260 swarms in two apiaries.

B. TAYLOR.

Forestville, Minn., Feb. 5, 1889.

First swarm of the season came out Feb. 15th.

Sara Sota, Fla., Feb. 17, 1889.

S. C. CORWIN.

From 4 stands in the spring, I increased to 30, and secured surplus in sections, 1000 lbs.

Edina, Mo., Mar. 12, 1889.

J. M. LONG.

I had 13 hives, spring count; increased to 22; extracted 100 gallons of honey; sold it at 75 cents per gallon.

S. C. CHARD.

Luling, Tex., Jan. 18, 1889.

FROM 19 TO 44; 13 QUEENS AND 840 LBS. OF HONEY SOLD.

In 1888 I commenced in the spring with 19, and increased to 44, fall count. I sold 13 queens, and took 840 lbs. of honey.

J. W. TAYLOR.

Ozan, Ark., Jan. 13, 1889.

FROM 26 TO 48, AND 5100 LBS. OF HONEY.

My account with the bees for 1888 is as follows: I started in the spring with 26 colonies; increased them to 48, and obtained 5100 lbs. of honey—1400 lbs. comb, and 3700 of extracted.

Salt Lake City, Utah.

WM. G. ADAMSON.

3850 LBS. OF HONEY FROM 50 COLONIES, SPRING COUNT.

During 1888 we secured from 50 colonies, spring count, 3850 lbs. of comb honey—an average per colony of 77 lbs.

JOHN AND JAMES COWE.

Goodland, Mich., March 7, 1889.

PROSPECTS GOOD; FROM 18 TO 22, AND 1000 LBS. OF HONEY.

I commenced the season with 18 stands of bees; increased to 22, and obtained 1000 lbs. of comb honey in 1-lb. sections.

J. B. RIGGENS.

Swanton, Neb., Feb. 18, 1889.

A POOR SEASON, BUT 3000 LBS.

Last year was not very favorable. I got 3000 lbs. of honey this year. I am wintering 100 swarms in a cave. Thus far it has been very warm in the cellar. It is colder and snowing to-day. Thirty colonies are out of doors.

T. KOULO.

Portville, N. Y.

WINTERED WELL, AND GATHERING POLLEN.

My bees wintered very well on winter stands. The majority of the hives are full of bees, and they have all been gathering pollen for the last three days, from black elder. I have 25 colonies, all in good condition.

S. YINGST.

Sydney, Pa., Mar. 18, 1889.

ENCOURAGING FOR CALIFORNIA—SEE PAGE 207.

I have just finished trimming and plowing my orchard. The peach-trees are commencing to bloom, and the oranges are getting nice and ripe. I noticed the bees bringing in pollen to-day, and the queens commencing to lay. So far we have had 11 inches of rain, and the grass and weeds are growing very fast. We must have an abundance of both early and late rains, however, to insure a good honey crop.

J. F. MCINTYRE.

Fillmore, Cal., Jan. 7, 1889.

THE FIRST POLLEN.

How pleasing to the eye and ear to witness the return of the first pollen-laden bees of the season! How eagerly they rush out, and how business-like they march in, after reaching the alighting-board! Such a sight I had the pleasure of witnessing to-day. My 100 colonies have all wintered, and are in good shape, but are rather short of stores, the mild winter being the cause of a greater consumption of stores than usual.

W. H. LAWS.

Lavaca, Ark., Feb. 14, 1889.

NOTES AND QUERIES.

We solicit for this department short items and questions of a practical nature; but all QUESTIONS, if accompanied by other matter, must be put upon a SEPARATE slip of paper with name and address.

BEES DYING OFF IN EARLY SPRING.

I HAVE 3 hives of bees, and on warm days the bees come out in big lots, and die. What can I do for them?

JAMES M. SMITH.

Perkiomenville, Pa., Mar. 4, 1889.

[Those bees which fly out and do not return are probably old bees. They probably would not be of very much service to the colony any way, and would likely die in the hives if not outdoors before actual weather comes on. Apiarists generally calculate on having some of these old bees, at least, die early in the spring. They will accumulate on the bottom-board if the colony is in the cellar, or will fly out on the first sunny day if on their summer stands packed in chaff.]

WHY WE DISPENSE WITH THE TIN RABBIT IN THE DOVETAILED HIVE.

I like your dovetailed hive, as shown in GLEANINGS for Mar. 1, but I don't understand why you do not use the tin strip, or rabbit, for frames to rest upon, as it renders the manipulation of the frames much more rapid.

R. Q. KING.

Springfield, O., Mar. 6, 1889.

[Because the majority of the honey-producers, those who are extensive bee-keepers, prefer to dispense with the tin rabbit, for the very reason that the latter allow the frames to shuck about too much in transportation from one out-apiary to another. Hives having frames resting on wood bearings require no special provision to hold the frames in moving. See Question-Box, this issue.]

WHAT IS A FAIR COMMISSION FOR SELLING HONEY?

I am starting a home market for selling my honey. Most of the groceries in this town sell it for me. I furnish every thing, show-cases and paper-boxes, stands, and cases for extracted honey, and all they have to do is to sell it out. Now, the question is, what per cent do you think is right to allow the grocers for selling it for me?

MRS. W. G. TITTSWORTH.

Avoca, Ia., March 3, 1889.

[Under the circumstances I think that 5 or 10 per cent would be all your groceryman should charge; but friend Heddon and some others have suggested that grocerymen will work much harder to make sales, and to work honey off, where they have from 20 to 25 per cent, than where they get only from 5 to 10.]

CAN CHLOROFORM BE USED SAFELY ON BEES?

I lately read an article, saying that chloroform might be used with safety in quieting bees, when handling them; but I thought best to refer to you before making the attempt; and as I presume other readers of GLEANINGS would like your opinion, would you please give it through the columns of your excellent magazine?

MRS. S. ALLCOCK.

Ashtabula, O., Mar. 12, 1889.

[Bees can be chloroformed so that they will fall down on the bottom-board, or stick to the combs, apparently dead. The idea is very old; but I believe that one after another who have tried it have decided they would much rather have live bees to manipulate than dead ones. Smoke is very much handier and cheaper, and at the same time accomplishes the purpose far better than chloroform.]

61 BUSHELS OF JAPANESE BUCKWHEAT FROM 24 LBS. OF SEED.

I bought a bushel of Japanese buckwheat of you last spring; sold half of it to a neighbor, and sowed the remainder, just 24 lbs. It made a wonderful growth of straw, and was, without exception, the

nicest field of grain I ever saw. Bees did not work on it to any profit, and the seasons are far between that buckwheat amounts to much in this vicinity, for honey. The frost came early, damaging the crop of grain at least one-third. I harvested 61½ bushels, heaping measure at that.

Norwich, N. Y.

W. B. NORTON.

THE TARANTULA A GREAT JUMPER.

In GLEANINGS, p. 123, is a drawing of a tarantula. There are some here at least twice as large as the drawing (it may have dried and shrunk before it was received by Prof. Cook), but these will attack any one who molests them. I have seen them jump twelve or fifteen inches high, and eighteen to twenty inches in a single jump; and I believe Prof. Cook would think there was danger when one would jump several times after him and clear eighteen inches each jump.

S. H. COLWICK.

Norse, Tex., Feb. 26, 1889.

WOULDN'T STAY IN THEIR NEW HOME.

I bought a swarm of bees from a tree last summer, and brought them home and divided them and put one part in one small hive of Italians, and the other half in another stronger colony. The last half contained the queen from the tree. I supposed the Italians would kill the black queen, but they stayed in the hive until after 12 o'clock, then every black bee came out and ran away with their queen.

H. J. HANCOCK.

Siloam Springs, Ark., Feb. 22, 1889.

[It is never safe to presume that the bees will kill one of the queens, for they quite often behave just as you have described.]

OUR QUESTION-BOX.

With Replies from our best Authorities on Bees.

All queries sent in for this department should be briefly stated, and free from any possible ambiguity. The question or questions should be written upon a separate slip of paper and marked, "For Our Question-Box."

QUESTION 115.—*a. If you were obliged to keep the same number of brood-frames in a hive the year round, how many L. frames would you use in working for comb honey? b. For extracted?*

b. 24.

R. WILKIN.

Eight.

H. R. BOARDMAN.

a. Seven; b. ten.

G. M. DOOLITTLE.

Eight; sixteen.

A. J. COOK.

a. b. Eight frames.

GEO. GRIMM.

a. Eight; b. nine.

MRS. L. HARRISON.

I use ten for both.

P. L. VIALLO.

a. Eight; b. ten in the lower story.

O. O. POPPLETON.

Seven for comb honey and sixteen for extracted.

E. E. HASTY.

Not less than ten, both for extracted or comb. We prefer 11 or 12.

DADANT & SON.

I believe I would use ten for either comb or extracted honey.

A. B. MASON.

With my present knowledge I am inclined to think a. eight; b. ten.

C. C. MILLER.

For comb 8, and winter in the cellar. For extracted 24, and winter outdoors (on 16).

E. FRANCE.

If I were obliged to start anew, and to use L.

frames, I would make all hives to hold eight frames. For extracted honey alone, I would a little rather use ten frames.

JAMES A. GREEN.

a. If I were using the kind of hive in which I was obliged to retain the same number of frames continually, I should like it to hold the equivalent of about seven of our 10½x16 frames. b. I wouldn't consent to any such arrangement for extracted honey.

P. H. ELWOOD.

For boxing, 9. If the question means that no other combs are to be used for surplus in extracting, I would not advise trying to secure extracted honey, as more box honey could be secured than one could expect of extracted. If surplus combs are to be added by tiering up, I would use the same number in both cases.

L. C. ROOT.

If I were obliged, I would keep 10 frames in the brood-chamber, no difference if my object were comb or extracted honey, because from a large brood-chamber I expect a large colony, more honey, and fewer swarms; while from a small brood-chamber, only a small colony can be expected, less honey and more swarms. If I should keep a certain number of frames all the year round, my standing as a bee-keeper would not be above the level of an old fogey.

C. F. MUTH.

Should not your question read, "Brood-frames in the brood-chamber" instead of "in the hive"? The hive combines the whole arrangement, both brood and surplus departments. In the brood-chamber I would use just eight L. frames, no more and no less. I speak assuredly on this subject, for I have given it very extensive tests on a large scale, the question being a hobby of mine for years. There are advantages in having a large brood-chamber, but there are also disadvantages, which amount to more than the advantages, unless the brood-chamber is horizontally divisible. I speak for both comb and extracted honey, and of the brood-chamber strictly.

JAMES HEDDON.

I suppose the above question was intended to call forth opinions in regard to the matter of a hive made wide enough to hold eight or ten frames. Father Langstroth decided on ten; but almost immediately certain parties thought eight was sufficient. A great many who made a business of selling bees at so much a colony preferred eight, because they are easier to handle. Of late, however, there has been so much said about having a chaff division-board outside for winter, and then a dummy to contract the space when the bees are storing honey in sections in the summer time, that a great many of us have been obliged to ask whether a hive wide enough to hold eight frames is not enough. Of course, there is danger of letting bees starve where we have only eight combs in the brood-chamber or lower story; and a good many will prefer a hive to hold ten frames on this account. An eight-comb hive is easier to handle, because you do not have to reach so far over. There is also quite a saving in expense, because a narrower board will do for covers and bottoms, and they are less trouble to handle. The bees are also more likely to put all their surplus honey in the sections above, for there is but little room to store it below when the combs are well filled with brood.

With an eight-frame hive, however, we must many times begin feeding as soon as the surplus honey is removed from above. This is especially the case with black bees; so you see, friends, it depends much on the kind of man as to the number of combs we should have in the brood-chamber.

QUESTION 116.—*Do you prefer the closed end or hanging frame? Give reasons.*

I have never used any closed-end frames.

O. O. POPPLETON.

Hanging frames, because they are so much easier to work with.

P. L. VIALLO.

The hanging frame, on account of greater ease of manipulation and less injury to bees.

R. WILKIN.

I use and prefer the L. hanging frame, and prefer it for ease of manipulation.

MRS. L. HARRISON.

Hanging frames. I think they are more easily handled, and more perfect in their adjustment.

H. R. BOARDMAN.

I prefer the hanging frame. There are many reasons, but chief among them is ease of manipulation.

GEO. GRIMM.

Hanging for L. frames—that is, in a common L. hive; the combs can be moved so as to make room to get out the first frame.

E. FRANCE.

Hanging frames. Principally because they are more easily manipulated, and are not so liable to kill bees during manipulation.

G. M. DOOLITTLE.

I prefer a hanging frame, for I work mostly for extracted honey, and I want to remove them readily. In my locality, or perhaps I should say with my bees, every thing gets glued fast that it is possible for them to fasten.

A. B. MASON.

Hanging. I think I should like the warmth of the closed ends, but I think the hanging frames so much easier to handle, and it is possible to move them so as to vary their distances apart. I must confess, however, that I never had much experience with closed ends.

C. C. MILLER.

I prefer the hanging frame. To gain entrance to the other kind is too much like breaking into a burglar-proof safe; and to get out of the scrape and close up, one adds wholesale murder to burglary. Possibly familiarity with some better form of the closed-end frame would mollify me somewhat; but I do not think I shall ever be won over.

E. E. HASTY.

We have tried the closed-end frames, but we killed and enraged bees every time we opened the hives. At one time we crushed a valuable queen, and then resolved never to use these frames again. The theory of manipulating hives instead of frames can not hold with the pure Italian bees, which cling to the combs so much that it is impossible to shake them off.

DADANT & SON.

I want neither closed ends nor closed top-bars to my frames, because a glance will tell me where, in winter or spring, the cluster is, or where I may find the queen. No bees need be killed by taking out or replacing the frames, which can not be avoided if the frames have closed ends or closed top-bars, not to speak of the slower, unhandier process of manipulation with the latter.

CHAS. F. MUTH.

Hanging. Greater ease and convenience of handling. I am still in doubt about the Heddon hive. While it is certainly an admirable hive for the expert, I am not so sure for the beginner. I am not ready to recommend it yet for all.

A. J. COOK.

I prefer the closed-end frame, because it is better to winter and spring bees in, because it can be as easily and rapidly manipulated as any, and it kills as few bees as hanging frames, and because it is the best hive for moving bees in. The new Quinby hive, which we use, can also be contracted to suit the requirements of the smallest colony, or enlarged for the strongest, without any extra division-boards or extra pieces.

P. H. ELWOOD.

I prefer the closed-end frames as used in connection with the new hive; and my reasons in general are, that, with the arrangement, I received the numerous advantages long ago claimed which only closed-end frames can give, and at the same time do away with the past objections to closed-end frames which really overcame their advantages as compared with hanging frames. I deem this department too limited in space to go into an enumeration, or describe all the advantages and disadvantages.

JAMES HEDDON.

I very much prefer the closed-end frame, whether standing or hanging. The first reason is the fact that each space retains its own warmth so much more than when open; and I find, when tested side by side, that, in early spring, I can build up light stocks that would be lost with the open-end frame. Capt. Hetherington once said to me, that he had saved 100 stocks of bees that spring that would have been lost had he used the open-end frame. I believe one of the greatest secrets of success in Julius Hoffman's management is in his use of a frame closed part way down with enameled cloth, pressed down upon the top of the frames.

L. C. ROOT.

I prefer a closed-end frame for my use. Such a frame is, perhaps, not advisable for one who is rearing queens or selling bees by the pound, nor for the learner to gain knowledge and experience most easily. But for the production of honey as a business, in large apiaries, by those who have already served their apprenticeship, I believe closed-end frames have decided advantages. While they are not as movable as metal-cornered hanging frames, they are sufficiently movable for all practical purposes, and they are immovable when you want them so. A hive full of combs may be handled as though it were a single piece instead of a collection of loose pieces, thus saving work, worry, and time. You are not obliged to stop to space the frames every time they are handled. When a swarm is hived in them you know the frames are at the proper distance, and can not slide together, producing crooked combs. If you use foundation in wired frames, your combs will all be built straight, even if the hive should not stand exactly plumb. In carrying, handling, hauling, or shipping, the frames do not need to be fastened, yet can not slide together, killing bees and queens.

JAMES A. GREEN.

Before I read any of the answers to the above question I knew pretty well how it would go. Out of 18 answers, 14 are in favor of hanging frames; but the other 4 are men of such wide experience and reputation

as honey-producers as Elwood, L. C. Root, Heddon, and friend Green. Perhaps friend Green has not produced the crops of honey that the other three have, but he is a bright, progressive young bee-keeper. I am a little astonished at him because I didn't know that he used the closed-end frames at all. Were we in a convention I should be a little fearful that we might have some speeches in regard to this matter that would be a little unkind. Perhaps not, however, for conventions of late years have got into a way of being very courteous and charitable, even though some few should have ways of working, and ideas, that seem to the larger number beyond comprehension. I can readily understand why a bee-keeper should consider the closed-end frames best; and I can readily imagine how Capt. Hetherington saved 100 colonies by having closed-end frames; but I confess I can not understand why our good friend Elwood can say the closed-end frame "can be as easily and as rapidly manipulated as any." Now, I do not mean to dispute this statement at all, mind you; and I can readily believe that, with his long practice with them, he can get along faster himself than with hanging frames; but I very much doubt whether those of us who have always used hanging frames could ever learn to work closed-end frames as rapidly as he does. I have long been thinking of visiting our friends in York State, in the height of the honey-flow; and perhaps I may some time have the pleasure of seeing our good friend Elwood work; not this season, however, for I have promised to visit the basswood fields of Wisconsin.

QUESTION 117.—*If you use all-wood frames, do you prefer to have them hang on metal rabbets or on a plain wood bearing, in the production of honey?*

There is little difference. DADANT & SON.

On metal rabbets every time. O. O. POPPLETON.

I prefer them to hang on a metal bearing.

L. C. ROOT.

I should prefer a metal rabbet, with Hoffman frame, as next best to an all-cased end.

P. H. ELWOOD.

On a plain wood bearing. Then they are always ready to haul, without fastening the frames.

C. C. MILLER.

I use the all-wood frames hanging on tin rabbets—too much propolis to have frames on wood bearings.

P. L. VIALLO.

I would never have metal corners, and on the whole I think I would not have even metal rabbets. I have only wooden rabbets now.

A. J. COOK.

I use all-wood frames hung on wood bearings. Metal rabbets are a source of constant annoyance to me, and the few that I had I have discarded.

GEO. GRIMM.

We use all-wood frames, with wood bearings. I don't see how either way can make any difference in the amount or quality of the honey.

E. FRANCE.

I use the wood-bearing. After years of experience along this line, I think there is little difference in favor of either kind of bearing, when taking all things into consideration.

G. M. DOOLITTLE.

I use metal rabbets, and could not be induced to go back to the wood-bearing.

A. B. MASON.

Metal rabbets, by all means—and I use metal corners too. If we believe in movable frames, let's have movable frames, and no swindle about it.

E. E. HASTY.

With either hanging or fixed frames I always use all wood; but when I use the hanging frames I prefer a plain wood rabbet in the brood-chamber, and a simple metal rest in the extracting supers.

JAMES HEDDON.

I use wood bearing, for the reason that I have the bearings notched for spacing the frames; then my frames are always the proper distance apart. Frames hanging on metal rabbets are easier to manipulate.

MRS. L. HARRISON.

There is not much difference between a rabbet of wood or one of metal; but I prefer my all-wood frame to rest on a metal rabbet, but not on the sharp edge of the tin. I do not want my frames to rest on a plain wood bearing.

CHAS. F. MUTH.

I prefer to have them on metal rabbets, especially in the upper story. I do hate to be prying frames loose every time I have to move them; but in lifting off the upper story I sometimes wish the lower frames were held down by propolis.

R. WILKIN.

I always used metal rabbets with the ordinary hanging frames; but with the closed-end frames I find them unnecessary. The ordinary all-wood frame in a wooden rabbet is not as readily handled as a properly made closed-end frame, yet it is not as secure as the latter.

JAMES A. GREEN.

All the hives that I now have in use have the metal rabbets; but I am almost tempted to say that, if I had it to do over again, I'd have none of them in my hives. It takes a long time to find out, sometimes, the real value of an "improvement."

H. R. BOARDMAN.

This question, too, like the one before it, depends much on what one is going to do with his bees. If he is going to raise queens, I feel quite certain that he will make money by having metal rabbets and metal corners. If he is going to raise comb honey, and have out-apiaries, so that the bees are to be frequently moved several miles, I think quite likely he does not need either metal rabbets or metal corners; and it would not be surprising to me if he ultimately decided on a closed-end frame, especially if he is working for comb honey. I have visited many beekeepers of late years, who say they have hives in their apiaries from which the brood-combs have not been removed in years. If that is the way we are going to manage, we can not only dispense with metal rabbets, but we may have closed-end frames, and a few have been bold enough to say there is no particular need that we should have frames at all—just have a shallow brood-chamber, something like Heddon's, and let the combs be built in solid. So you see that much depends on the habits of the owner, and what he is working for. To tell the truth, I, years ago, planned a box hive. You will find it in the old volumes of GLEANINGS, and I have studied on the matter considerably at different times of late years.

OUR HOMES.

Thy way is in the sea, and thy path in the great waters, and thy footsteps are not known.—Ps. 77:19.

CONTINUED FROM LAST ISSUE.

THE friends will remember that I left off at our last issue where the guide was just ready to take me to the cave. The strong door was unlocked, and the guide handed me a lamp. Just then, however, I remembered that I was thirsty; and as I did not want to travel through the cave in that condition, I asked the guide if we could find any water to drink, in the cavern. He replied there was none. Furthermore, there was none at the office by the entrance. He said the only thing they had was some Manitou spring water, in bottles—15 cents a bottle. Don't be uncharitable, dear friends. That is about the way they do things at all these fashionable resorts. I decided, however, to pay the price, even if the water does run away in a quantity large enough to run a small sawmill, right at the foot of the mountain every day in the year. As it happened the water was bottled from the same spring I tasted the day before, that I thought was not very good. The cork flew out of the bottle with a pop that might have satisfied any schoolboy; and as the guide poured it into the glass, it fairly smoked and sparkled with foam. Good? Why, my friends, it was about the most delicious drink I ever tasted in my life. Don't ever say again that *stolen* waters are sweet. They will not compare with that which has been honestly paid for, and the thirst for it earned by hard work in climbing mountains, and, above all, taken with a clear conscience, and with thanksgiving to God, the great creator of the mountains and springs, and all the wide universe. While I remarked that one glass was plenty for the time being, I noticed he corked the bottle and set it down by the side of the telescope. The water is so pungent you can take only a swallow at a time. He says they have an arrangement for bottling it under pressure before it reaches the surface of the ground.

And now for the Manitou Cavern. It is much like Mammoth Cave, only on a smaller scale. Before we had gone into the mountain many feet I uttered exclamations of surprise at the beautiful white alabaster icicles, for that comes nearest in description of any thing I can think of. Each icicle had a drop of crystal water hanging to its tip, and these drops of water glistened like so many stars. Where the water trickles down them fast enough to fall off, stalagmites are seen right under them. The very old ones have grown brown and gray with age; but the new ones are glossy, and bright with the liquid that encases them and makes them grow. Of course, like every one else I wanted one to take home as a specimen. But the guide told me that, if they had not decided to shut down on every demand of this kind, their cave would have been ruined in no time. I admitted this, and yet it seemed rather hard that I could not have just *one* little one. Well, a good many

times the guide takes a dozen or more people in at once. Some of them, of course, will persist in loitering behind, and these are the chaps who snap off the icicles, and carry them away. In fact, during this past season the matter has become so bad that they have been obliged to cover all the finest ones with a protection of poultry netting. I confess that the sight of the netting around these beautiful products of nature does not seem to be just in harmony; but what are they to do? The guide stuck his cane through one of the openings in the netting, and gave one of those beautiful icicles a rap. I supposed that he would, of course, send it flying. But instead of that it rang out like a bell—the sound echoing and reverberating away through the galleries of the cavern. Again and again he struck others in the same way. They did not break, but every one of them gave forth a musical note. Some of them sounded like a silver bell, and this is the peculiar feature of Manitou Cavern. Further on, the impregnated water had run down the side of the cavern, and coated it with a polished covering.

"This is what we call the 'Wet Blanket,'" said the guide; and he hit it a clip with his cane. It rang out, too, like a great bell. During the wet season of the year this impregnated water sometimes forms pools on the floor; and as it runs over the edges it forms this white alabaster stone. As it rises higher and higher it makes the edge of it a basin, with many islands in the center, all incased in alabaster. As we passed under some vast domes above, that seemed to go away up toward the top of the mountain, a reverberating roar, rising and falling like the tones of an æolian harp, arrested my attention. I stopped and asked for an explanation. He said it was a sort of echo or reverberation of the sounds in the cave. I could not be satisfied, however. I gazed up at the rocky vault above, then up one gallery and down another, and finally I began to consider a sort of quizzical look on the face of my guide.

"Look here, old chap, you are humbugging me a little. Aren't you making that sound with your mouth?"

He laughed, and admitted that he was. But I forgave him, especially as it was so wonderful to think that a feeble human voice could awaken such a frightful roar as that. The guide is something of a musician, as I will tell you presently, and he had discovered that, by striking the keynote of that dome, he could almost make the whole mountain vibrate, as it were. As it is a difficult matter to keep his voice in perfect unison with the vibrations of the dome, he would occasionally waver to a little lower note and then higher, and thus caused the roar to rise and fall, in a way that seems almost startling. We now came to some wooden seats, and the guide asked me to sit down while he gave us some music. As I composed the whole audience, I spread myself, as it were, to do justice to the occasion. He climbed some stairs to a grotto above and some distance away from me. Then he remarked, by way of apology,

that dame Nature had not builded their organ exactly as he would like to have it, therefore he was obliged to do the best he could under the circumstances. I was fully agape, not only with eyes, but mouth wide open. Said organ was only a collection of stalactites, but, to tell the truth, it did look somewhat like a great pipe-organ. Some of the bass pipes were perhaps a foot through, old and gray with age, while the highest notes were made by striking with his cane some of the smaller delicate white icicles, such as I have described, and I tell you the music was not only funny but good. The heavy bass was not quite in tune, but it rather added to the performance to hear some of those great fellows "grunt," as it were, their part of the melody. I believe he played five different pieces in all—Green-ville, Yankee Doodle, and a simple melody for which I know no name except that we used to call it "My Father and Mother were Irish."

saw the Cauliflower Garden, where dame Nature is growing cauliflowers of alabaster. They just grew up, and were all formed from a damp rock. Alabaster stars were growing on the walls of the cavern in many places where it is damp, and I am told that a damp fog that is seen in some places deposits this white carbonate of lime on the walls and ceilings of the cavern. Many other things not mentioned here were not particularly different from Mammoth Cave, in Kentucky. This cavern, however, is so high up in the mountain that there are no rivers or lakes such as Mammoth Cave furnishes. Its special attraction is the beauty of the stalactitic formations. Many of them are so translucent, that, when your lamp is held on the opposite side, they look very much like a coal of fire, and every one of them, big and little, gives forth these musical notes.

When I got out of the cave I was ready for the rest of that spring water, corked up

THE PIPE-ORGAN OF MANITOU GRAND CAVERN.

The concluding piece on the organ was an imitation of the Swiss bell-ringers, and some parts of it were almost complete. If you shut your eyes you would imagine you saw the performers as they threw their bells on the table and picked up others during a rapid performance; and yet he does it all with simply a couple of sticks, selecting the proper stalactite from among the confused group, just as nature has placed them. I clapped my hands and stamped my feet, but I felt that I was not able to do justice to the occasion.

On our way out we passed the North Star, which shone from the depths of a cavern to which we could not well gain access. The guide explained it as simply a drop of water on the bottom of a stalactite. Then I

in the bottle. I also had another good look through the telescope. Although the building is very securely made, right on the rock, every footstep on the floor shook the instrument so that Pike's Peak seemed toppling as if they had an earthquake. When I spoke about going to the top of it, the guide said no one could get up there at that season of the year. The rocks and every thing else were covered with ice, and it was intensely cold. When I reminded him of the smoke coming from the chimney, he said the U. S. Signal Service requires a man to stay there for the purpose of scientific observation. Down the mountain I started again, and ere long I was at the foot of Rainbow Falls. Now, although the sun shone forth brightly, and the water poured

over the fall to my full satisfaction, not a speck of a rainbow could I see. Perhaps it was not the right time of day.

Before ten o'clock I was down in the town again. As I passed a livery stable I asked them how low they could give me a horse and buggy to drive over to the Garden of the Gods. Their very best figures were \$3.00. When I expostulated a little in regard to \$3.00 for two hours' time, they kindly consented to let me stay till half-past twelve. That was the greatest concession I could get. I remembered the time when I saved a dollar an hour in walking home, when the train left me; and just now it occurred to me that I could make more than a dollar an hour, and I did not feel tired one bit. I started off on foot, and alone—no, not alone, for with every step I took in that strange weird place, I felt *God's presence, his peace, and his love* in my heart, and I was *exceedingly happy*.

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

ALL ABOUT RAISING SWEET-POTATO PLANTS; ALSO VERY COMPLETE DIRECTIONS FOR MAKING HOT-BEDS FOR STARTING VEGETABLE-PLANTS OF ANY KIND.

IN answer to my inquiry, a short time ago, for a paper on raising sweet-potato plants, 32 very good papers were sent in. These were carefully read over, and portions of a good many were used, besides using some of the communications entire, as you will observe. I aimed to give all the valuable points communicated, and at the same time avoid as much as possible all repetition. As these papers come all the way from as far south as Mississippi, and clear up to Michigan in the North, it is quite interesting to notice the varied methods adopted in consequence of the difference in climate. We start out with a paper from a friend in Michigan.

HOW TO GROW SWEET-POTATO PLANTS IN MICHIGAN.

Friend Root:—I have been growing sweet-potato plants more or less all my life, and here, for 24 years past, frequently 100,000 plants in a year. I used to live in Southern Illinois, where we grew plants readily without glass, using boards or any kind of covering at night and in stormy days, and leaving the beds open in day time when the weather was fair. Of course, the time for bedding the potatoes will need to be varied so as to suit each man's locality.

Good seed potatoes are of the first importance; and if not already on hand they should be ordered of a reliable party, as near by as possible, so that they need not be long in transit. Most reliable seedsmen will furnish such potatoes as are best suited for bedding-out purposes; but on no condition buy potatoes that have been exposed for sale in the city markets, as they are liable to have been so chilled as to cause them to rot, as they will not safely bear a lower temperature than 38°.

I usually bed sweet potatoes about April 15th to 20th, and order potatoes shipped a few days earlier, so as to have them ready at the desired time. If the weather is not favorable delay it a few days, as

exposure to cold in shipping is risky. Use fresh horse manure for making the bed; that is, such as has not already been heated and the heat expended. It should be prepared a week or ten days before the bed is wanted, by piling it up and moistening it, if not already moist, so that the heat will become thorough and uniform throughout the pile by the desired time.

If the ground is porous, so that it will not hold water, a pit may be dug, 18 in. or 2 ft. deep, into which the manure should be evenly spread and carefully packed down, so that it will not settle out of shape, and so that the heat will be uniform as possible. A frame of the desired size made of any cheap lumber that will not warp badly, should be set over the pit or bed of manure. This frame should be about 9 inches deep in front, and 15 on the back (the end pieces being sloped to match), so that the sash will have pitch enough to shed water. In this frame fill three or four inches of good fine soil, evenly spread directly on the manure; then place the sash on the frame, and, after the heat has become uniform, and is found to be all right—usually in two or three days—the potatoes should be placed evenly over the surface of the bed—not quite touching each other, and covered with two or three inches more of good fine soil that will not bake—a sandy soil is preferred; then replace the sash and keep a close watch that it does not become hot enough to burn the potatoes. I have never used a thermometer, but I judge of the temperature by thrusting my fingers down through the soil in various places. Sweet potatoes require a strong bottom heat at the start as they are liable to rot. Just so it is safely below the burning-point is all right.

I use sash 3x6 ft., and four of these sash will cover a bed 6x12 ft., which will usually afford accommodation for one barrel of potatoes, if they are of about an average size. If small, more room will be required. I seldom split potatoes, as they are more liable to rot; but if large, so as to require splitting, the round side should be placed down. One bushel of good seed sweet potatoes should give 5000 good plants, if every thing goes well, and the plants are removed as fast as ready; sometimes more than that number, but oftener less.

After the potatoes are placed in the bed, and the sash are on, constant care must be exercised to see that every thing goes right. The bed will require airing more or less every day from 8 or 9 A. M., to 4 or 5 P. M., especially if the sun shines; but they should be closed during the night; and if it is cold enough to freeze, the sash should be covered with mats, old carpet, or any thing that will protect from the cold during cold nights or stormy days. As the season advances, and the weather becomes warmer, the sash should be removed entirely during the warm part of the day. If this is neglected, the plants will become "drawn"—that is, tender and worthless for planting. About a week after the potatoes have been planted they will begin to throw out roots and show signs of growth, at which time the bed should be well sprinkled with water, and this repeated as often as necessary to keep the ground in good moist condition. As the bed fills up with plants, a large amount of water will be required, usually a painful under each sash every evening, if the weather is sunny and warm. Good plants will usually be ready in three or four weeks from the time of bedding the potatoes.

If the ground is such that a pit would hold water better, make the bed entirely above ground, simply banking up to prevent the escape of heat from the sides of the bed, or a frame may be made deep enough to contain both the manure and the soil under and over the potatoes. D. C. EDMISTON.

Adrian, Mich., Feb. 25, 1889.

KEEPING SWEET POTATOES FOR SEED AND FOR PLANTS.

First, dig sweet potatoes, intended for seed or for keeping, before any frost kills the vines. Dig on a clear day, if possible, so the tubers may dry well; after lying in the sunshine, remove to an out-room and spread out to cure and evaporate superabundant moisture. Should quite cool weather come on, cover with old blankets or carpet. On no account must the temperature of the tubers get down to 32°, or you will not need a hot-bed for that lot of tubers. On approach of freezing weather we pack in barrels and remove to a room that is warmed so as to not fall below about 40°, keeping the barrels open to air. They are packed in the barrels as apples are, with no packing between them. They should be handled so as to bruise as little as possible. We remove our seed tubers to the sitting-room which is warmed pretty regularly all winter, on the approach of severe weather. We generally keep about two barrels of tubers over for seed, and seldom lose more than $\frac{1}{4}$ bushel out of the lot. I have repeatedly tried keeping tubers in my cellar, a very nice dry warm one, but they invariably rotted before spring.

About the last week in March we get our hot-beds ready, using forest-leaves and strawy manure, principally leaves, as we have them in abundance close at hand, and the process of fermentation and heating goes on much slower, and lasts much longer, than with all straw manure. We tramp this heating material down a foot deep at least, and cover with about 5 inches of soil, composed of pure sand, woods-earth, and coal-braes from old charcoal-pits. I presume any good rich loam will answer, the blacker the better, as it will absorb the sun heat better. Put on sash and heat up; and as soon as the ground is warm through, which can be found out by running the hand down in the soil, put in the tubers, sinking them at least 1½ inches below the surface. Give the beds all the sun heat they can get, even until they fairly steam. Sweet potatoes will not germinate well unless kept very warm and moist. If plants come on too soon for your market, pull off as soon as 5 or 6 inches long, and "heel in" in nice fine earth, keeping shaded and wetted for a few days until they strike root, after which they are the best for transplanting. Should they be kept too long in this condition they will commence forming little tubers, after which they are useless for planting, as they will not throw out a second set of tubers. I would especially caution against using such plants. The large tubers we place in the hot-beds by themselves to sprout; and, as soon as started, we split them in two, plant the cut side downward, so as not to have long dangling plants. If large tubers are cut in halves before they begin to sprout they are liable to rot. I would on no account cut them before. Tubers should be 4 or 5 inches apart, so as not to crowd the plants. Plants should all be pulled as soon as 5 or 6 inches high, as long plants are not desirable; and to allow a new set to grow. We sometimes have

4000 to 6000 plants heeled in before a single plant is sold, and grow from 20,000 to 40,000 per season.

The sweet potato is a lover of heat; and if you want a nice lot of plants, their bed must be kept quite warm. Cloth shades are of no use; use only sash with glass, and cover the sash at night with old carpets, rugs, or matting, or even plank, to retain the heat, much of which would be lost through the glass.

□ To recapitulate: Tubers must be kept warm and dry, and not fall below 40° in temperature. Hot-beds must be made quite warm, and kept so, and beds kept stripped of plants over 4 or 5 inches above ground. Last season was very unfavorable for hot-beds, as the weather was cloudy most of the time, and surface heating was of little avail. We could have sold 100,000 plants had we had them, as many beds failed to germinate, on account of a lack of heat. We have been growing plants for market for ten years.

E. G. KINSELL.

Green Spring Furnace, Md.

USING CLOTH TO COVER THE BEDS, ETC.

Friend Root:—I have been engaged in the business to some extent for the past 20 years. The manure of which the bed is composed should be forked over a time or two besides the handling it gets in hauling from the stable and unloading where the bed is to be constructed. About the first of April (I write for my latitude) I find early enough to build the bed. I use a pit about 12 inches deep, in which I place about 15 inches of manure from the horse-stable. Here I would say, that, should it contain a great deal of straw, it will need more forking. The object of the extra forking is to get it thoroughly mixed. I scatter over the bed, treading down evenly and firmly. My beds are designed to take a frame made of three 16-foot boards for the sides, 12 inches wide, one board in front, two at the back, with sloping end-pieces 5½ or 6 feet long. The bed, or pit, should be one foot larger every way than the frame. The above size will hold about one barrel or 2½ bushels of potatoes as they should be bedded. I place ribs, or cross-supports, about 2½ or 3 feet apart, to support the canvas, which I make of heavy unbleached sheeting, a yard wide, two widths stitched together about 5 yards long, requiring 10 or 11 yards for one frame cover, costing 8 or 9 cents per yard. Now, to avoid the trouble you speak of I tack one of the long sides to a light straight piece of board, usually 3 or 4 inches wide, one thick, the other side and two ends being supplied with light rings about ½ inch in diameter, sewed in loops on the cover about 2 feet apart, which are to be hooked over nails tacked in the frame to hold the cover on the side on which the roller is attached (for such it is) is also secured in a similar manner. Whenever it is desired to give the bed an airing, unhook and roll back as far as desired, not unhooking any further back on the canvas than you wish to roll. Of course, if the day is warm enough the end rings can all be unhooked, and the cover quickly and neatly rolled to one side, secure from any ordinary wind. I next place from 4 to 5 inches of soil on it. From the 10th to the 20th of April is soon enough to bed the potatoes. My experience leads me to say more potatoes are ruined by being placed in a bed too hot than one too cold. It is best, of course, to avoid either extreme. It is to be understood, that good sound seed is advised. Level the soil nicely, free from lumps or clods; place the potatoes from

$\frac{3}{4}$ to 1 inch apart, parallel over the bed, not letting them touch anywhere, splitting those that are $1\frac{1}{2}$ inches or more in diameter, placing the split side down. Cover about three inches deep, with good mellow soil. After the plants appear, which will be in 12 or 14 days, give water as needed. If placed closer than above, it is a hard matter to remove the plants without destroying too many young ones. About 4 or 5 weeks from the time of bedding, the plants will be ready to draw. As to varieties, Yellow Jersey and Yellow Nansemond seem to give the best satisfaction here. I usually get from 6000 to 8000 plants from a bushel of seed from the above varieties. I formerly tried saturating my canvas with linseed oil, for the purpose of making it waterproof, more transparent, and durable. I soon discarded the practice, as I found it utterly useless, as, after that time in the spring, we are not apt to have very long-continued cold weather, and the bed should be protected by shutters or plank to keep out cold and heavy rains. In no case should it receive a heavy cold rain early in the season. The oil has a tendency to rot and cause the canvas to break, thus proving an injury instead of a benefit.

Any one who has had experience in making hot-beds will soon learn that, the fresher the litter the more violent the heat, and sooner it will need forking over to prevent fire fang, which will be in from two to three days, four at most, from the time of first hauling.

W. H. GRAVES.

Duncan, Ill., Feb. 18, 1889.

RAISING SWEET-POTATO PLANTS, ETC.

About twenty years ago I was a grower of the plants quite largely, sending plants one season into 23 different States. Greenhouses are too damp; as a general thing fire heat otherwise. At least I did not make a success of it, though I believe it has been done on quite a large scale. The simple hot-bed, that there has been so much written about, yet no one ever made two that were just exactly alike in all their workings—too hot or too cold, too wet or too dry, weather not just to our liking, something the matter, that nothing but the best judgment could get along with and bring out the best results—as I was going to say, the simple hot-bed is the best, just as you would make it for any purpose, with three or four inches of good compost on top; then take the potatoes, if not over one inch in diameter, without cutting; spread them over the bed about as far apart as the size of the potatoes, keeping away from the edges of the bed four to six inches; then cover one to two inches with the same rich compost, screened so as to be uniform in consistency, and of a material that will not pack. Now cover the bed with boards (I have seldom used either glass or cloth for sweet potatoes); watch close; the temperature wants to be just about the same as for tomatoes, cucumbers, etc. As soon as the plants appear, which should be in about ten or twelve days, add one to two inches more of compost, so that the entire depth will be three to four inches. Now you can commence to give a little water—very seldom any is needed on the bed until the plants appear. They must now have plenty of air; and as the time is supposed to be some time in May, they will need but little covering except nights.

The usual time for putting the potatoes in the beds is from the 10th of April to the 1st of May; and for setting the plants, from the 20th of May to

the 10th of June, in this climate. I have raised excellent plants in a very mild hot-bed on a sheltered hillside sloping south, putting in the potatoes the last days of April, without using any covering whatever over the bed, and had the plants ready for setting the first days of June.

Potatoes larger than an inch in diameter I cut lengthwise through the middle. They will bring more plants, and quicker, than whole potatoes; but there is more danger of their rotting in the bed than whole potatoes. The rotting of the potatoes is caused by cold-dampness, and lack of air when the bed is too warm.

To keep the potatoes over winter, harvest carefully before frost kills the vines; spread in some dry place a week or so, then pack quite tightly together in dry barrels—old flour or cracker barrels—up to two inches of the top, then put on clean dry sand that will shake in and cover the two inches left; store in a dry place, and keep the temperature at 60 to 65 all the time.

You know enough about the management of hot-beds and every thing else, for that matter, to know that no amount of instruction either written or verbal will bring success. Nothing but experience will bring the needed knowledge, and that to a few only.

D. CUMMINS.

Conneaut, O., Feb. 18, 1889.

Friend Cummins also incloses a copy of one of his old circulars. As it contains much additional information, we give it below:

CULTIVATION OF THE SWEET POTATO.

Light sandy or loamy soil is best, but heavy soil well drained, with plenty of coarse manure well worked in, will do very well. Plow and harrow well; and if your land is poor, plow light furrows about three and a half or four feet apart; scatter in them a quantity of partly rotted manure, throw two furrows together over the manure so as to have the ridge quite high, and not very broad on top. Unless rain has fallen within twenty-four hours, or the soil is quite wet, it will pay to water when setting out, which may be done as follows: Thrust the right hand into the ridge (a mason's or garden trowel would be better), draw it toward you, and with the left drop the roots at the back of the hand or trowel; draw the soil around the roots; pour in about half a pint of water, then fill up with soil so the plant will be an inch or so deeper than it stood in the bed, so the stems of the lower leaves will be covered, as then it will sprout again if cut by frost or worms. Set the plants from fourteen to sixteen inches apart; keep clean from weeds, and the soil mellow with cultivator and hoe. Raise the vines with rake or fork to prevent rooting at the joints; the more moist the weather, the more frequently it will need be done. Dig if possible before severe frosts; store in a warm dry place—a damp cellar will not answer. With good cultivation the crop will average three hundred bushels per acre. Plants will be ready by the 15th of May, and can be set from that time until the 1st of July. One year I set a small patch the 25th day of June, in very rich soil, the yield of which was at the rate of over six hundred bushels per acre. My plants are grown entirely without glass, and are very hardy; they will be carefully packed so as to go hundreds of miles in good condition.

THE FOLLOWING IS FROM THE FRIEND WHO TOLD US HOW TO RAISE \$10.80 WORTH OF GRAND RAPIDS LETTUCE ON 12 FEET SQUARE OF GROUND.

Raising sweet-potato plants for sale has been right in my line of business for the past 14 years. I have always raised them in hot-beds. My frames are 6 feet wide by 12 long; front of frame, 8 inches high; and back, 12 inches high, covered with four 3 x 6 sash. For heating material I use fresh horse

manure, with considerable straw and forest-leaves thoroughly mixed and thrown into a large heap to heat. When it gets steaming hot I fork it over into another heap to heat up again, by which time it is ready for the bed or pit, for I dig a pit 2½ feet deep and 6 inches larger every way than the frame. Into this pit I shake the material, being careful to get it in as evenly as possible, at the same time treading it down solid and building it up 6 inches above the level of the ground, banking up the outside with dirt to keep the heat from escaping sideways. I now set the frame on and put on the sash. Now the bed will heat up the third time, and we must wait a few days until it cools down; for if we put the potatoes on while it is too hot they will surely decay, and the whole thing will be a failure. I watch it very closely with a thermometer, by plunging it down deep into the bed; and when the heat recedes to 90° or a little below, the bed is ready. I now put on four inches of good rich garden soil, and firm it down with a board, and put the potatoes on as thick as they will conveniently lie and not touch; then if one rots it will not affect the rest. I cover with 2½ inches of the same soil that is under them, being careful to have it moist and in good condition. Bank up the outside of the frame a little higher than the dirt on the inside, and raise the frame up so as to give the required depth under the sash. Now on goes the sash, and nothing remains to be done but to give it air on sunny days. I never water until the plants come through the ground. The above plan is for high ground. If the ground is low and wet, the pit must either be drained or the bed must be built on top of the ground.

ORSON TERRELL.

North Ridgeville, O., Feb. 23, 1889.

RAISING SWEET POTATOES AND SWEET-POTATO PLANTS IN RUTHERFORD CO., TENN.

Editor Gleanings:—Thousand of bushels of sweet potatoes are annually raised in this, Rutherford County, and many persons make the production a specialty, and several farmers raise nothing else to sell, and depend solely on the potato as a money crop. In our latitude, Middle Tennessee, about the last of March or first of April they are bedded for "slips." A variety known as the Southern Queen, a white or rather light-pale yellow, is almost universally planted. A raised bed is to be preferred to one even with or below the surface of the ground; and if protected on the north by a plank or close stake fence, the better. In bedding 40 or 50 bushels, a rich loose alluvial soil is selected, and plowed or forked up to the depth of 10 inches; if deeper, the better, and beds 4 feet wide are formed with ditches or walks 12 or 14 inches wide between, made by spading or shoveling the earth upon the beds. These walks give room for stepping around in drawing the slips, without tramping the beds, and also keep the beds well drained and free from too much moisture and subsequent baking. This plan is practiced by large producers for field cultivation, and the potato is not bedded until all danger from frost has passed—or the beds protected—and enough is bedded to set the whole plantation at the first drawing, which is generally about the first of May.

If a great number of slips are desired from one or a few bushels, make a raised hot-bed. In the absence of cottonseed, which we have and use here, fresh stable (horse) manure, well tramped to the

depth of 4 to 6 inches, is as good, and upon which pour as much water as the manure will absorb; then cover the manure with rich, well-pulverized mold, to the depth of 2 inches, upon which place the tubers as close together as you wish, then cover with two or three inches of like rich mold, and let the bed have all the sunshine it can get, but let no water, and especially no cold rain, fall upon it; it must be protected with boards, plank, canvas, or glass, when first made, which can be removed on warm sunny days. When the sprouts begin to crack the ground, add 2 inches more of earth. This will give the sprouts a long shank, and upon which numerous lateral or fibrous roots appear, and which assist the plant in keeping alive when detached from the potato. When the plant begins to come through this second layer of earth, give the bed a good watering; if the weather is warm, use pond water or well water that has stood several hours in the sun, or, what is still better, the suds from the wash-tub. Sometimes weeds and grass start before the plants, which may be removed with a sharp weeding-hoe.

When the plants are from 4 to 6 inches high they can be removed from the bed, and set out; or, if too cold, "heel" out, as nurserymen term it, in large bunches, for a week or two, as they keep better and produce more roots than if set out singly in the garden or field. Before drawing the slips the bed should be watered, which makes the drawing easier, but do not use too much water, or enough to make it muddy. The slips are drawn with the right hand, and not too many at one pull, the left hand pressing the potato, keeping it in place. When but few are drawn at a time they break off easily near the potato. If many are pulled at once, the skin is broken and frequently a plug of the potato comes with the slip, which materially diminishes the next supply. I have raised very nice potatoes from slips set out as late as the 1st of July. The months of July, August, and September being seasonable, potatoes may be harvested about the 1st of October.

If your potatoes are sound, and the weather favorable, in 8 days after removing the slips the bed will again be full and ready for the second drawing. The bed will allow several drawings before the potato becomes exhausted and refuses to send out more sprouts or slips, if kept well watered in dry hot weather. The plants should not be set in the field until the cold rains are over. They become chilled, and are never afterward vigorous, and will not produce good-sized tubers. The preparation of the soil, planting out, cultivation, and subsequent digging and housing of the crop, is reserved for a future paper if desired.

W. P. HENDERSON.

Murfreesboro, Tenn., Feb. 19, 1889.

THE KIND OF SOIL TO PUT OVER THE MANURE IN THE HOT-BED.

On the hot-bed you use *very sandy* soil. I have been in the habit of going down to the river (our place has a long river-front of half a mile); along this, sand is constantly deposited in time of freshets; the whole bank is made up of it. I take this and put it on 4 to 6 inches deep, and lay the potatoes on the bed, almost touching each other, covering them over 2 or 3 inches. You are raising cuttings really—you don't want food for plants. What they want they can find in the sand, as there is enough soil to furnish all they need. In break,

ing off the plants, be careful to put one hand on the potato to keep it in place, and break off with the other, so as to allow the younger ones to grow.

JOHN L. JANENBY.

105 West Walnut Lane, Philadelphia, Feb. 2, 1889.

HOW TO RAISE SWEET-POTATO PLANTS IN MISSOURI.

I have been in the business for several years, and I bed as many as 100 bushels. I dig my pits about 14 inches deep, 7½ feet wide, and about 40 feet long, as that makes as much sheeting as I can handle easily. I board up the north side 3 feet high, and slope my canvas to the south; pack in the manure about 12 inches deep; when packed solid, use plenty of straw, if you want it to heat well.

Skidmore, Mo., Feb. 23, 1889. JAMES PARSHALL.

USING CLOTH FOR A COVERING, AND HAVING IT SLOPE BOTH WAYS.

If a large bed is wanted we sometimes make the frame level six inches above ground; put a light ridge-pole through the center, then draw the muslin over like a house-roof, tucking the ends down at the gables. In this way the length of the bed should be north and south, giving the sun an equal chance on both sides of the roof. Here in Central Illinois we make our beds about April 15th.

Philo, Ill., Feb. 21, 1889.

M. L. BREMEN.

USING WHEAT OR OAT STRAW TO CONFINE THE HEAT OF THE MANURE.

On the manure place not less than 3 inches of light soil, on which put your potatoes, and cover about one inch deep; then over the whole bed place wheat or oat straw about 6 or 8 inches deep, and cover with boards to keep out rain. Be sure to feel under the straw every morning early; and as soon as the heat gets to the top, open the bed every day and cover only with straw at night, and in about two weeks the sprouts will be seen coming through the ground, when two inches more dirt should be put on the bed, and the straw removed entirely. This plan gives me first-class plants in 5 weeks from the time of planting, and they can then be drawn every 8 or 9 days until July.

E. F. BUSICK.

Church Creek, Md., Feb. 19, 1889.

USING STRAW OR LEAVES WITH MANURE IN ORDER THAT THE HEAT MAY BE LASTING.

I put in the trench about two feet of fresh stable manure, and it should be about half straw or leaves, otherwise it may get too hot and burn the potatoes.

If you use glass you want to be careful when the sun shines very hot, or you will cook the whole batch. The glass should be taken off when it is very warm, and put on again at night.

I built a house 14x16, double walls, and filled in with sawdust. I have kept my sweet potatoes and honey in the same house, keeping the temperature at 60° above; and if I haven't had well-ripened honey, no one ever did.

JASPER SMOCK.

Terre Haute, Ind., Feb. 25, 1889.

USING HAY AND BOARDS AS SUBSTITUTES FOR GLASS.

Care should be taken that the manure be all heated alike throughout the whole bed when first put in. Just as good plants can be grown without using sash, by covering the bed to the depth of 12 or 15 inches with marsh hay, and using covers over this made of ½-inch boards. The bed must be watched

closely; and when the heat is likely to get too high, air must be given by taking off the board covers, and a part or all of the hay if need be. If the plants are likely to get too large at top before you wish to set them in the field, mow the tops off.

Exeter, Pa., Feb. 26, 1889.

P. SUTTON.

The following is from a friend who gave substantially the directions given by the rest. He adds in conclusion:

I have tried this plan for several years, and it has never failed. I sold nearly 30,000 plants last year, and then did not have enough. I also make my beds for sprouting early cabbage, celery, pepper, and tomatoes after the above plan, only I bank up on the outside and cover with glass.

Darlington, Ind.

THOS. N. STOKES.

FORCING SWEET-POTATO PLANTS BY MEANS OF HOT SOAPSUDS.

We force potato-plants sometimes as follows: On washdays, after the washwoman is done with the warm suds we give our potato-beds a good bath, and it makes the plants come right up.

Water Valley, Miss., Feb. 20, 1889. W. H. EMBRY.

A VISIT TO BEE-CELLARS IN NORTHERN OHIO.

ERNEST OFF ON A RAMBLE.

FOR a long time I have contemplated visiting H. R. Boardman and other bee-keepers in the vicinity of Norwalk, O. This opportunity did not come until the last week in February.

The principal object I had in making this visit was to study the comparative merits of outdoor and indoor wintering. As you are aware, for the past two years we have had uniform success in wintering in chaff, and as a matter of course incline toward the outdoor method. H. R. Boardman has been equally successful—perhaps more so than we—in his winter repositories.

On the morning of the 26th of February, I found myself in Norwalk. It is with this place that many of our old readers will associate the name of our old friend S. F. Newman, who for a good many years back has been quite an extensive bee-keeper. At one of the leading groceries I saw some very nice honey, stamped with the name of the man whom I wanted to see. The groceryman informed me that Newman's honey *always* sells, and that he would buy no other. It was not long before I was introduced to the gentleman himself, whereupon I was invited into his office above the store. He is an insurance agent, and, like a good many other bee-keepers, has other business in connection with bees. He employs a clerk to do copying and general writing in the office, and a competent man to take care of his bees while he himself gives his personal supervision to both departments of the business. He has some three out-apiaries. After talking awhile, Mr. Newman kindly invited me to visit his bee-cellar, and, of course, I accepted. On our way thither Mr. Newman said:

"I believe that Boardman has got the way of wintering bees. Although I have

had excellent results in wintering in chaff hives, I believe I shall in time winter all my colonies on his plan."

We arrived at Mr. Newman's house; and after a welcome by the family I was conducted to his bee-cellar—a back room partitioned off from the main cellar. In it he has 127 colonies, all of which seemed to be wintering nicely, with one or two exceptions.

"You see," said Mr. Newman, "I have got tight bottom-boards; but if I were to get another lot of hives I would have the bottoms loose; and I would pile the hives up in a repository just as Mr. Boardman does, without bottom-boards, leaving the latter on permanent stands."

Of course, there was the strong odor of ordinary wintering repositories.

"From what source do you get your ventilation?" said I.

"From no source at all."

"Don't you have an underground sub-earth ventilator?"

"No sub-earth ventilator. There is an opening," said he, pointing to a small window in one corner, "that I used to use; but you see it is now plugged up tight."

"And your cellar-door is tight, is it?"

In response he closed the door and left us in absolute darkness, showing just the way he left the bees. As we left the repository Mr. Newman said:

"It is a mystery to me how that man Boardman carries his hives into the cellar without the bottom-boards. It seems to me the bees would be dropping and flying out, to the discomfort of the carrier."

"Yes, I should think so too; but I am going down to East Townsend to-morrow, and I am going to find out just how he does it."

Mr. Newman is quite enthusiastic on the matter of out-apiaries.

"Why," said he, "last summer my bees in the home yard had done little if any thing. Things went on thus, even through the summer. At my Bronson out apiary I discovered that the bees were filling up on something. This proved to be nectar from the peavine clover, of which there were large quantities in fields near by. They not only filled up, but were actually storing surplus. During this time my bees at home were doing little if any thing."

"How much of this peavine-clover honey did you secure from this apiary?" I asked.

"Three thousand five hundred pounds, nearly all of which was gathered after the basswood season closed; and it is the same honey which you admired in the store when we first met. I have noticed before," he continued, "that a difference of only a few miles makes a considerable difference in the secretion of nectar at times."

The swarms in the Bronson apiary were hived upon empty frames, and so far Mr. Newman is pleased with the plan.

After a pleasant chat with the family, I left. The following morning found me *en route* for East Townsend, or, rather, Collins, as the Railroad Guide has it. It seems to me unfortunate that there should be one name for the postoffice and another for the

railroad, both designating the same place. As Collins is only a short distance east, I am soon at the station. Upon inquiry I find that I must go directly south—following that long walk southward I saw yonder. After going but a short distance I inquired of a bright-looking school-boy, with books under his arm, where I might find the residence of H. R. Boardman.

"Well, sir," said he, "you go straight ahead until you come to the postoffice. Then you turn to the right, and go down that street until you find a whole lot of bee-hives, and then you turn in."

"Thank you," said I, with assurance. "It is the man with a 'whole lot of hives' whom I wish to see;" and with such directions I should certainly have no difficulty in finding the place. A short walk brought me to the postoffice; and upon turning to the right I saw a man who looked very much like a bee-man I had seen a few times at conventions. He was "the man who never loses any bees." Although I had not given my friend any warning of my expected visit, I could hardly have called upon him at a more opportune time. He was on his way to the postoffice, and, being a little "under the weather," as he said, he was rather yearning to see somebody to talk with. On approaching his residence I found no bee-hives, but a "whole lot of hive bottoms."

"Then you do leave those out the year round?" said I, as we were entering the house. The morning was a little chilly, and the warm base-burner fire, which greeted me as I sat down in an easy-chair, was cheerful indeed.

Glancing about me while my host was disposing of my coat and hat, I discovered some beautiful specimens in taxidermy—some 200 specimens I should guess. There were stuffed birds and quadrupeds, as natural as life could be, from this and adjoining States. Among the number were some quite rare specimens, all of which was the work of friend Boardman during his spare hours in winter or other times when his bees did not demand his attention. He enjoys it as a hobby, and well he may. He is, without doubt, a close student of nature—not only with the little busy bee, as I shall presently try to show, but with all animate creation.

While we were talking I could not help noticing the affiliation between a cat and a dog, lying at our feet, the former sleeping quietly across the dog's paws, as affectionately as a—couple of lovers, although the dog, when he observed that our attention was directed toward them, did not seem to regard the intrusion of his feline friend with favor. A low growl announced that he was seemingly ashamed to be seen in such company. The cat gave no particular heed, but, on the contrary, rubbed against her companion as though she understood him. I did not fail to notice the intelligence of all the dumb animals around friend Boardman. Even the horses were bright, and seemed to know their master.

THE DOVETAILED HIVE.

THE new dovetailed hive seems to be taking well, for orders are beginning to pour in for it at a good rate. At the solicitation of some practical beekeepers we have made the Dovetailed T super with thick ends, thus throwing out the objectionable loose boards to take up the waste space in the end. The section-holder super is also made deep enough to leave a full bee-space above the sections. W. Z. Hutchinson, whose advice we have sought, says, in a private note, "With the changes you have made the hive is well nigh faultless." He prefers the new Heddon hive, but next to it he says stands the Dovetailed hive as we now make it. We are now making some new engravings to illustrate it as modified, and will give illustrations and further particulars in our next.

Many questions come in to this effect: "Will the Dovetailed hive take the Simplicity frame, and will it take the $\frac{1}{2}$ -depth wide frame?" It will take the Simplicity or Langstroth, to be sure; but the supers will not take the half-depth wide frames. We can make them deeper to take the half-depth wide frames if desired, but we shall have to charge some more.

MORE ABOUT SWEET-POTATO-PLANTS.

I HOPE the friends will not complain because we have made this so much a sweet-potato number. The principles that are taught by the many letters apply not only to raising and starting plants of any description, but they are valuable to anybody who is interested in or who has any thing to do with the garden or with agriculture; and I want to give you two more letters that are furnished by R. M. Reynolds, of East Springfield, O. The following was from Waldo F. Brown, in the *Ohio Farmer*, some years ago:

The great danger in sprouting is, that you get them too hot and scald the potatoes. I lost a large part of my potatoes for several years from this cause. . . . I found, finally, that, when my bed had just the right degree of heat, a thick covering of straw or corn-fodder would keep an even temperature, so that it would not be chilled by cold nights, nor scalded by the hot sun; and since I adopted this plan I have had little trouble in sprouting sweet potatoes. Leave the bed open in the middle of the day until it feels warm, and then cover closely, and it is probable that your bed will need no more attention until the plants begin to come through. . . . As the straw will prevent evaporation, the bed will not need watering until the sprouts appear, when it should be kept well watered until they are nearly large enough to set out. I think it hardens the plants at this stage to let them get pretty dry, but the bed should be thoroughly watered a few hours before the plants are drawn.

And here is another, from Alfred Rose, of Yates Co., N. Y.:

The potatoes should be covered with three inches of fine dry sand (sand is much preferable to loam, as it is warmer and cleaner); there will be a difference of a full week or ten days between beds covered with sand or loam, those covered with sand coming the earliest. After the sand, then cover with as fine dry straw or hay as can be procured, then the beds should be covered with boards in such a manner as to shed rain.

THORBURN'S BUSH LIMA BEANS, ETC.

On page 209 of our last issue, I told you I had written to Thorburn, asking him how many packets he had that he would let us have at 25 cts. each. His reply was, that he was sold out. I then wrote that we *must* have just a few, no matter what they cost, to which he has made no reply. If no reader of GLEANINGS can help us, I shall put an advertisement in *Popular Gardening* and in *American Garden*; and I feel sure that I can in some way strike one of Thorburn's customers. I am going to offer their weight in gold for a few of them, if I can not get them otherwise. All I can find out about them is given on page 209, March 1st. A bush lima bean has been hunted up away out in Minnesota (advertised by Northrup, Broslin, Goodwin & Co., Minneapolis), but they are of a deep creamy yellow color, and but little larger than Henderson's.

We have at this date, 8544 subscribers.

SPECIAL NOTICES.

THE IGNOTUM TOMATO.

If any subscriber has omitted to ask for his tomato seed, or if any one has failed to receive his package, make application at once and it will be mailed to you.

COLD-FRAME CABBAGE-PLANTS.

With the aid of our new cold greenhouse, we have secured a splendid lot of H. A. March's cold-frame Jersey Wakefield cabbage-plants. Price 10 cts. for 10; 80 cts. per 100; \$6.00 per 1000. If wanted by mail, add 5 cts. for 10, or 25 cts. for 100.

CLEOME INTEGRIFOLIA, OR ROCKY-MOUNTAIN BEE-PLANT—SEED WANTED.

Since Samuel Wilson's advertisement of this California honey-plant, notwithstanding our caution—see page 148, a demand for the seed has sprung up that has exhausted our supply. Now, then, if any of the bee-friends in California or elsewhere have some seed to spare, we should be glad to get it. Please mail us a sample, and tell us how much you have and what you want for it. My impression is, that the demand will be short-lived. By the way, we should be very glad indeed to get reports from those who have tried the plant.

SEED POTATOES.

Our seed potatoes have wintered nicely, and are not sprouted a particle at the present writing. Early Ohio, Early Pearl, Lee's Favorite, and Empire State, we offer at 75 cts. per bushel, or \$2.00 for a barrel of three bushels. Beauty of Hebron, and Burbank, we offer at 50 cts. per bushel, or \$1.25 for a barrel of three bushels. In ordering potatoes we will pack them in our new slatted potato-box for 10 cts. per bushel extra. The potato-box, you know, is worth 16 cts.; but we make the above deduction because it saves providing some other package. The box will be worth 16 cts. to almost anybody. Where you are so far away that express and freight charges are quite an item, we will send potato-eyes, postpaid by mail, at 10c for 10; 80c per 100, or \$6.00 per 1000, of any of the above varieties.

PRICE LISTS RECEIVED.

Since our last issue we have received price lists of queens, bees, and apianian supplies in general, from the following parties, who will be glad to furnish them to applicants. Those marked with a star (*) also deal in fine poultry.

A. E. Manum, Bristol, Vt.
J. M. Hyne, Stewartsville, Ind. (closing out his stock).
J. A. Nelson, Muncie, Wyandotte Co., Kansas.
C. Hooper & Co., Northampton, Northumberland Co., Pa.
W. P. Beach, Ovid, Clinton Co., Mich.
J. C. Sayles, Hartford, Washington Co., Wis.
Ransom & Culver, Quincy, Mich.
Wakeman & Crocker, Lockport, N. Y. (section-formers only).

No. 1, \$2.00; No. 2, \$1.75; No. 3, \$1.50 Knife,
No. 4, 1.25; No. 5, 1.00; No. 6, .65 \$1.15

On receipt of the above price

SMOKERS AND KNIVES

will be sent postpaid. Descriptive circulars will be sent on receipt of request card.

Bingham & Hetherington Smokers and Knives are staple tools, and have been used ten years without complaint, and are the only stovewood-burning clear-smoke bee-smokers; no going out, no vexation. Address

BINGHAM & HETHERINGTON, Abironia, Mich.
Please mention GLEANINGS. 671db

North-Shade Apiary.

Full colonies and nuclei at 50 cts. per comb, in good 8-frame L. hives (no charge for hives). Tested Italian queens, \$2.00 each. No queens for sale, except to go with bees. Will ship in light shipping-boxes instead of hives when so ordered. My brood-frames are Simplicity, L. size.

DISCOUNTS:—\$25 to \$30, 10 per cent; \$30 to \$50, 15 per cent; \$50 to \$75, 20 per cent; \$75 to \$100, or larger orders, 25 per cent off from above prices.

CONDITIONS:—All colonies will be well stocked with brood and bees, all healthy and bright. Delivered f. o. b. cars at Alamo, in the best possible shipping order. No foul brood ever known near here. Will fill all orders first week in May. Remit by Am. Exp., money order, registered letter, draft on New York or Chicago, or by P. O. money order on Kalamazoo.

Address

O. H. TOWNSEND,

Alamo, Kalamazoo Co., Mich.

7d

P. S.—40 to 200 acres of good land, located in Gratiot County, Mich., for sale cheap. The best location I know of for bee keeping. For further information, address as above.

SUSPENDERS FOR BEE-KEEPERS.

A number of customers have requested us to get a good suspender for bee-keepers, and a number of kinds have been suggested. The one shown above, called the "Foster," suits us as well as any we have seen. If you notice carefully you will see that, by the use of eveners, or equalizers, the strain on each button is the same. We can furnish them made of good white elastic web cotton ends, at 35 cts. per pair; silk ends, 50 cts. By mail, postpaid, 5 cts. per pair extra. In ordering please call them the "Foster." We can furnish very good white elastic suspenders, without the eveners, at 25 cts. per pair; by mail, 5c extra. Adjustable elastic armlets, 10c per pair, postpaid. A. I. ROOT, MEDINA, OHIO.

EGGS FOR HATCHING, from choice S. C. B. Leghorns; can fill all orders promptly, great and small. Circulars free. A few O. I. C. pigs for sale. 41-5d
FILLMORE DECKER, New Florence, Westm. Co., Pa.

With Love at the helm, a successful voyage may be expected. In the guidance of our beautiful little craft, "THE BEE-KEEPER'S REVIEW," Love sits supreme. In other words, we are most thoroughly in love with our work. With feelings akin to a mother's, do we look upon the numbers of

the REVIEW. They are our mental children. It is said, that, although all the children of a family receive affection in the same degree, there is always a favorite child. This may not always be true; but certain it is, that every author of more than one book looks with special pride upon some one of these books. Reader, if you would be pleased to see the number of the REVIEW that comes the nearest to an ideal, send for the March No. for 1889. It will be sent free, and with it will be sent the May and June issues for 1888. Price of the REVIEW, 50 cts. a year. Back numbers furnished.

The Production of Comb Honey is a neat little book of 45 pages; price 25 cts. This book and the REVIEW one year for 65 cts. For \$1.00 the REVIEW will be sent two years, and the book "thrown in." Stamps taken, either U. S. or Canadian.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

FOR SALE.—30 black and 40 hybrids, which I will sell after the 10th of April at the rate of 10 of each kind each week, till all are sold. Price, black, 30 cts.; hybrids, 50 cts. J. W. POOLE, Russellville, Ark.

I have 8 or 10 hybrid queens that I will take 40 cts. each for, or 4 for \$1.50. Ready to ship now, or I will take trade for queens. J. W. TAYLOR, Ozan, Ark.

I have two black queens, young and prolific, which I should be glad to sell at 35 cts. each.
B. C. GRIFFITH, Griffith, N. C.

Mismatched Italian queens for sale at 25 cts. each.
L. A. KESSLER, Nappanee, Elkhart Co., Ind.

Brown queens, 25 cts. Italian hybrids, 30 to 40 cts. Carniolan hybrids, 50 cts. each. F. C. MORROW,
Wallaceburg, Hempstead Co., Ark.

I have about 15 black and hybrid queens, ready April 15. I will ship in Peet cage, at 40 and 50 cts. each, safe arrival guaranteed. R. H. GUTHRIE,
Powhatan, Lawrence Co., Ark.

JOHN GRAND,

7-11db Batavia, Clermont Co., O.

In responding to this advertisement mention GLEANINGS.

BEE HAT AND VEILS.

Most people who handle bees wear some kind of a veil, or bee-hat, as some call 'em. Above we show the rig we prefer. The hat is one we have sold and recommended for two years, and have used for five or six. It is a light cloth hat, weighing only 1 oz.; fits any head, the inside rim having a rubber cord in it. The outside rim is held out in place by a spring wire.

We make veils of four different qualities.

No. 1 is our best veil, made of grenadine and silk brussels net, or tulle face.

No. 2 is the same without the tulle face, being all of grenadine.

No. 3 is made of mosquito bar, with tulle face.

No. 4 is made of mosquito bar, without the tulle face.

Price—	each.	10.	100.
No. 1, Best veil.....	\$ 75	\$6 00	\$55 00
No. 2, Grenadine veil.....	60	4 75	45 00
No. 3, Tulle-face bar.....	40	3 20	30 00
No. 4, Mosquito bar.....	25	2 00	18 00
Bee-hat.....	20	1 60	15 00

Sent postpaid, or with other goods, on receipt of price. Our veils are larger and more roomy than those of other makes that we have seen. They have a rubber cord in the top, to draw them tight around the hat, as shown in cut. The lower edge is bound with a blue ribbon, and is drawn under the suspenders, as shown. The grenadine veils will wear much longer than mosquito-bar.

BUCKEYE SASH-LOCK IMPROVED.

Since we first got hold of this most excellent fastener we have sold over 60 gross of them. This large sale shows how well they are liked. The last lot we received from the manufacturer are somewhat improved. By comparing the above cut with the one in our advertisement on the first inside cover page of this number, you will see that the change is in the lever. The old pattern has a knob, while the new has not. In most windows, as now made, there is a strip on each side, between the upper and lower sash, separating the grooves in which each sash is worked up and down. The improved lock can be fastened to the upper sash to press against this strip, and allow the lower sash, when raised, to pass it; while with the old pattern the lower sash would strike the knob on the lever. The lock as improved is absolutely perfect for either upper or lower sash. Price of the japanned, same as in the adv't, 5c each; by mail, 8c; 50c per doz.; by mail, 75c; \$4.00 per 100. We have them also made of solid brass at 10c each; \$1.10 per doz.; \$9.00 per 100.

A. I. ROOT, Medina, Ohio.

Vol. XVII.

APRIL 15, 1889.

No. 8.

TERMS: \$1.00 PER ANNUM IN ADVANCE; 2 Copies for \$1.90; 3 for \$2.75; 5 for \$4.00; 10 or more, 75 cts. each. Single number, 5 cts. Additions to clubs may be made at club rates. Above are all to be sent to ONE POSTOFFICE.

Established in 1873.

PUBLISHED SEMI-MONTHLY BY

A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS than 90 cts. each. Sent postpaid in the U. S. and Canada. To all other countries of the Universal Postal Union, 18 cts. per year extra. To all countries not of the U. P. U., 42 cts. per year extra.

OUT-APIARIES—NO. V.

RENTING.

AFTER settling upon a location for an out-apiary, make sure to have a distinct understanding as to the rent you are to pay. If the landlord says, "Oh! never mind, we'll not quarrel about that," leaving the matter to be settled some time in the future, don't leave it at that. There is a chance for a very wide difference of opinion as to what is right, and that difference will probably never be any less than when you start. Indeed, unless you know your man well it may be well to have every thing in writing. Perhaps I ought to add, also, that your man should know *you* well; and if you haven't already established a reputation for being a thoroughly upright man, I advise you to commence putting in 24 hours of every day, seven days in the week, working at it. It is difficult to give any advice about what rent should be paid, as so much depends on circumstances. If land is worth \$4.00 per acre, annual rent, and the presence of the bees makes no trouble whatever, I see no reason why the bee-keeper should pay more than \$4.00 per acre for the land he holds from cultivation. A tenth of an acre is sufficient ground on which to place 100 colonies, so that, in the case supposed, 40 cents would be a fair annual rent. But the flying bees may prevent horses from working anywhere near the hives, and thus, practically, the bees may occupy an acre or more of ground. Besides, the farmer may dislike to have the bees around, and \$40 added to the 40 cents would not reconcile him to their presence. Reference to page 946, GLEANINGS for Dec. 15th, 1887, will show what a diversity there is in the views and practices of some of our leading bee-keepers. Some

say the same price as the land could be rented for, for other purposes. Some say it depends on circumstances, and wisely decline to set any figure. Prof. Cook thinks the rent should be only nominal, as the bees are a benefit to the farmer. Dr. Mason says he can get plenty of places at \$5.00; \$8.00, \$10.00, \$15.00 to \$25.00, are mentioned by others, while Mr. Wilkin, in California, thinks \$100 is a moderate rent for a good location where 300 or 400 colonies can be kept with exclusive control of the bee-pasturage within a radius of three miles. Mr. France pays 25 cents for each colony, spring count. Dadant & Son pay one-fifth of the honey crop. This, however, includes not only rent, but house-room for extracting, for spare supers, boxes, crates, etc., and the board of men and team while at work. Capt. Hetherington, who is probably the largest out-apiarist in the world, pays uniformly \$15 for each apiary, and P. H. Elwood does the same.

From all this we learn that "circumstances alter cases," and also that in actual practice bee-keepers are very liberal in the rent they actually pay. I think this is decidedly advisable. The matter of rent forms a comparatively small part of the expense at any rate; and the good will of the family where the bees are kept has a cash value of considerable amount. I think I should always want to pay a *little more* than the farmer thought actually right. Be careful to manage so there shall be no annoyance from the bees on account of carelessness on your part. In my own practice I have never been able to have my landlords agree to take any regular pay. In two places I have relatives, so that in one case only was there a cold-blooded business transaction, and in that case it was hardly so after the first year, for Mrs. Belden insisted it was a pleasure to see us come; and here I may as well

own, that taking the women-folks along may make some difference in my case, for they always insist on having every thing picked up and in good shape about the apiary, and I'm afraid I shouldn't always be so neat.

In many little ways it is in your power to do things that will be pleasant, and will be a pleasure for you to do. If you've been reading a daily paper as you drove to Mr. Jones's, leave it at the house, and say you've read it and don't care for it. Mrs. Jones is pretty sure to like flowers. Take her some seeds or some slips. Unless you're a better bee-keeper than I am, you will occasionally have some of what I call "crooked honey," which the bees have built where you didn't want it, or in shape that you don't want, and you may as well leave it with Mrs. Jones. Don't take it to her and say, "I always like to be independent, and pay my way, so I brought you some nice honey," but go and ask her if she will lend you a plate or a milk-pan; then take her the honey and say, "Here's some honey that was in such shape I didn't want to leave it in the hive, and I'll be obliged to you if you'll use it for me. It will be a dauby sticky mess before I get it home, and I'd like to get rid of it." I've said that more than once, and told the truth too, and I'm pretty sure the crooked honey was appreciated. It would be a mutual pleasure, too, for you to go to the house early in the harvest and say, "Mrs. Jones, here's the first section of honey ever finished by the bees on your place, and I want you to see what nice work they make. Try it, and see if it won't be a good medicine for Mr. Jones." I might add that, although I pay no rent, I always make a point at each apiary of leaving all the honey I think the family need for a year.

C. C. MILLER.

Marengo, Ill.

Friend M., your concluding paragraph sounds so exactly like you that it seems to me I hear the tones of your voice, and catch the kindly look from your face as I read it. You are surely right; and the plan you give will not only enable one to get along nicely in establishing out-apiaries, but it will help us in every kind of business in the world. Nay, further: When the world's business and the world's busy cares are done, it will help you to lie down in peace, and be ready for the "Well done, thou good and faithful servant," as he is ushered into that better land.

WORKING FOR EXTRACTED HONEY.

FRIEND DOOLITTLE GIVES US SOME WISE HINTS IN REGARD TO THE MATTER.

BEFORE me lies a letter requesting that I give in GLEANINGS an article on "how to manage for extracted honey," saying, "Such a letter would be of great benefit to all novices." Of course, I desire to oblige and be a "benefit to all novices," but I can hardly see how the writer of this request knows that such an article would be a benefit to "all novices," for it is my opinion that the majority of them would not care a cent for it. However, as the time is at hand to begin to prepare for our season's work, it might be well to see what should be done if we are to work for extracted honey the coming summer. Just at the present time there seems to be a "craze" among bee-keepers on the subject of comb-honey

production, some of our bee-papers going so far as to inquire seriously if the "extractor ought not to go," claiming that it has been a damage to us as apiarists. I fear this is not a wise policy, for it can only result in soon lowering the price of comb honey and advancing the price of extracted, thus causing an expensive changing of fixtures a second time. It seems to me that the well-balanced apiarist should produce both comb and extracted honey; and as he sees the tide swaying toward the side of the one, he should go a little heavier in the opposite direction, but not enough so as to throw aside all his fixtures along the line the tide is moving. As I have worked for years for both comb and extracted honey, and believing that the present time is favorable to the production of more extracted honey and less comb, I will, in brief, tell the readers of GLEANINGS how I proceed to arrive at what seems to me the best results.

The first thing necessary in the production of extracted honey is a good queen to produce hosts of workers in time for the harvest. But good queens are of value only when we surround them with favorable circumstances, thus getting large numbers of eggs laid at the right time, and causing each egg to be nourished to a perfect bee, so that we can have the bees in our colonies by the tens of thousands at the right time. Failing to do this, the flowers will bloom in vain as far as filling our surplus combs with honey ready for the extractor is concerned. But, what are favorable circumstances? is asked, to which I reply, an abundance of food and warmth. The abundance of food is quite easily secured in this day of bee-feeders, and especially so if the apiarist has set aside, the previous season, as he should, combs solid with honey, which are ready to be set in the hive at any time. To secure the requisite warmth in early spring, I know of nothing better than chaff hives, such as I spoke of a month ago, which, together with chaff dummies for the weaker colonies, will give us the best thing possible along this line. If we do not have the chaff hives, dry-goods boxes or any thing made of rough boards to set the single-walled hives in and hold the chaff is better than no protection at all. Fixed in this way, colonies will go right on breeding during cold days and frosty nights where they would not think of doing so were no such protection used. The weaker colonies are to be confined to the combs they can occupy till they are filled with brood, when a frame of hatching brood is to be inserted in such a colony, taken from one of the strongest. Don't do this till they have the combs well filled with brood, for I find that a weak colony can be brought up to a condition ready to gather honey, much sooner by leaving it till in the condition as above, than it can by continual fusing with it in early spring. In this way, now work till all hives are filled with brood, which will be, if you have succeeded as you should, a little in advance of the honey harvest, or at about the time the main honey harvest is commencing.

If we wish no increase from our bees, no time is now to be lost in putting on the surplus arrangement, otherwise the bees become crowded and may get the swarming fever. For the extracting super I prefer another hive of the size of the first, but some prefer one of only one-half the depth. As to results, there is probably no great difference, but I consider it quite an object to have all hives and frames alike in the apiary. In putting on this sur-

plus arrangement I prefer to use empty combs, if possible, instead of comb-foundation. I also prefer to use two large or wide dummies, one at each side, for a few days, so that half of the room is taken up, which leads the bees along gradually instead of thrusting a large amount of surplus room upon them at once. As soon as the half of the hive given them is partly filled with honey, the dummies are taken out, the combs spread apart, and frames filled with foundation put between them. At this stage I would just as soon have foundation as empty comb, for the bees are now ready to work upon it, while before they were not. The time for taking out the dummies is when you see the cells being lengthened out with new comb built along the top-bars of the frames. How you will proceed in the future, depends upon whether you wish your honey ripened in the hive till the harvest is over, or ripened in a warm room by evaporation. Sometimes I think that honey left on the hive through the season is of better quality than that extracted every week or so; then, again, I am not so sure about it. Of one thing I am certain: More honey can be secured with less hives and fixtures where it is extracted when the bees first begin to seal it, than can be gotten by the other method. As to labor there is little difference, except that, when we extract often, the labor comes at a time of year when we are most crowded. To be sure, the operation is gone through with oftener; but to offset this there is little or no uncapping to be done, while the honey leaves the combs more clean with less than one-half the labor in turning the extractor. In my opinion the season has more to do with the quality of the honey than the process of ripening. If the season is hot and dry I would just as soon have honey extracted as above, as that left on the hive the season through. If damp and cool, I prefer it ripened by the bees, and even then it is not nearly as good as that gathered in a hot dry season. If you decide to leave all on to the end of the harvest, another story should be added just before the first is filled; but if not, the one extra story will probably be all you need.

In conclusion, I will say that the getting of multitudes of bees, just at the right time, has more to do with the successful working for honey than any thing else; and when all realize this, and work for the same to the fullest extent, one-half of the colonies now employed will gather as much surplus as the whole do under our present management.

Borodino, N. Y., Apr. 1, 1889. G. M. DOOLITTLE.

I believe I have nothing to add, friend D., except that I heartily concur in almost every point you make, and especially your concluding sentence.

RAMBLE NO. 14.

ON A (READING) SPREE. THE RAMBLER DISCOURSES ON THE EVILS OF INTEMPERANCE.

I HAVE had bee-keepers come into my apiary who were evidently on a spree from strong drinks; and it is a deplorable thing to see a man of intelligence and reason submit himself to this demon. But intoxicating liquors do not bring all the misery, and there are other sprees that seem to be nearly as bad. And, not to judge others harshly, the Rambler would commence with himself, and say that he is many times subject to sprees. Let him get hold of a good story, and day

and night it is pored over until finished; and what is that but a reading-sprees? The Rambler has no doubt that others who read this will acknowledge the same failing; and having in my rambles found an extreme case of this sort of spree, I wish to hold it up as a warning to those who may unconsciously cultivate the habit, to their detriment, instead of edification, and also to show that a reading-sprees will bring on nearly as bad results as the slavish use of the intoxicating cup.

A MAN WHO NEGLECTS HIS FAMILY.

The man whom the Rambler found, not only desired to read a book, but also to own it, so in the course of a few years his hard earnings went into a fine library of over 400 volumes, embracing works of fiction, history, science, and medicine. On any department of history he wished to post up; the most expensive books were purchased; he essayed to be a bee-keeper, purchased books and periodicals, and a general study of the business was entered into. The theory of bee-keeping was at his fingers' ends; but putting his knowledge into practice, a failure was the result. Division and re-division was made for rapid increase, with the usual result—ruination to the swarms. And another trial led to a failure in some other point.

The poultry business was taken up in the same way, with the same results. Meanwhile he took to himself a wife, and five children were born to them. These children are as bright and active as children will average, and, though living within five rods of the district school, the oldest have never been to school. Their education is neglected, to the carrying-out of some fine-spun theory about education. This man occupies a farm of 60 acres of good land which has been left by will to his children; he can not spend it, but can work it and support his family. Instead of working it, it has been much injured by successive renting; and at the present writing the wife is sick and is not expected to live. The children are in rags, except when clothed by kind neighbors, and all are thrown on the town for support. The father is strong and hearty—aged about 35, in the vigor of manhood. Is it any wonder that he is threatened by White Caps? While passing the house the Rambler and his traveling companion remarked that there was a house that looked as though an inebriate lived within—general dilapidation all around. The Rambler has found that, to be thrifty, a man must not be a slave to whisky or even to books. A book carefully and slowly read, and, better, re-read and marked, will give much

lasting benefit. There is a great amount of time thrown away upon even our daily and weekly papers. The Rambler reads many a paragraph before dinner that he can not remember after dinner, and he does not eat very hearty either. That we may all be free from frequent reading-sprees is the desire of the

RAMBLER.

Friend R., I have just been meditating on the very point you make, and I am really afraid that a good many of our young people are reading too much and practicing too little. The result of this kind of intemperance—for intemperance it surely is—is an ability to talk well on these subjects, and oftentimes to write very fair essays for the agricultural papers; but when somebody happens to pay a visit to the writer of these articles, and finds that his home does not correspond a bit with his preaching, it tends to demoralize and disgust the whole fabric of human society. Every one should read the books and papers, and know what is going on; but to continue to read and read, without actual practice, is just what you put it. In our own home we have a young lady who reads books until almost eleven o'clock at night, unless her parents interfere and make a fuss about it. As a result she is not ready for breakfast next morning. When I was her age I read pretty much every thing I could get hold of, but there was not enough to be had to give me a chance to be intemperate, as you put it. In this age of abundant periodicals, private and public libraries, etc., it does behoove us to look well to our children, and see that they do not acquire intemperate habits in the use of books.

CELLARS AND WINTERING.

PROF. COOK GIVES US A FAVORABLE REPORT OF HIS CELLAR DURING THE PAST WINTER.

MR. EDITOR:—Our old cellar was in sand, entirely below ground, and provided with good sub-earth ventilation. A good stream of water flowed into and out of that cellar constantly. I never knew the thermometer to go lower than 38° F., and I rarely knew it to go lower than 40. The bees wintered well. Our present cellar is in regular Medina clay, and this winter the thermometer has gone down to 35° F., repeatedly, and once down to 30° F., so that water froze in the cellar. I used an oil-stove repeatedly, and so kept the temperature for the most part up to about 40° F. My first point is, that a cellar in sand is better for bees than one in clay. I should think that the running water might have made the difference, except one very dry winter when the stream dried up. That winter was much colder than this winter has been, and yet 38° F. was the lowest in the old cellar. Again, the old cellar, or the house above it, was protected by a barn and evergreens. The present bee-house is on a bleak exposed hill. This situation may aid the clay. Were I to build a bee-house again, and could have my choice, I should select a sandy site. When the thermometer got down to 30° F., the bees were quite uneasy. I don't like such a low temperature in the cellar, so I was uneasy. Accordingly, last Tuesday, being a warm day, we concluded to give the bees a fly. We find them usually strong and in good condition. As in

the two past winters, the Heddon hive is far ahead. My assistant said every colony in the Heddon hives is as strong as they were in the fall. Most of the hives are covered only with a board, and have the entrances open. When set out, the covers were dripping with water. We fed most of them sugar syrup last autumn. I have never yet given just my opinion of the new Heddon hive since using it. I shall, with your kind permission, do it soon. It will not be all praise, but I am fully persuaded that the double brood-chamber, divided horizontally, is an advantage in cellar wintering.

I believe that Mr. Doolittle, if I remember correctly, found, a few winters ago, that the use of his oil-stove, to keep the cellar at the right temperature, was an expensive experiment. So I was somewhat nervous this winter. I am glad to report that our bees are bright, lively, with no smell of disease about their persons, and yet they were warmed by an oil-stove.

A. J. COOK.

Agricultural College, Mich., Apr. 1, 1889.

I have for some time been much of the opinion you express in the above, friend C., that a sandy soil is much better for a bee-cellar than cellars made in the damp cold clay. I should be glad to have a report from you, favoring a double-brood chamber divided horizontally. At this date, Apr. 11, Ernest has not yet taken his Heddon hive out of the cellar. He says he wants to wait until a week or two after just the right time, as Dr. Miller said at Columbus.

A QUESTION OF BREAD AND BUTTER.

SHALL WE COMBINE OTHER OCCUPATIONS WITH BEE-KEEPING, WHEN IT NECESSITATES A NEGLECT OF THE LATTER?

ABOUT a year ago there was some discussion as to whether it was better to market our eggs all in one basket, figuratively speaking. To give a little of my experience in the last year is the task I undertake.

My crop of 1887 was very small—the gross proceeds only a little over \$125, or about \$100 net. You see, without some other resource I should hardly have made a living that season. As it happened, I did not have to neglect my bees much during that year. But this last season, the case was different. My bees came out of winter well, but shorter of stores than ever before. The spring was so cold and cloudy that they hardly got three days' work on fruit-blossoms. I managed to bring them into summer in pretty good condition, however. Then day after day passed, first into weeks, then into months, as I looked anxiously. Was the failure an unmixed evil? I had other crops in, which I had employed a hand to cultivate. But he failed me early in the season. Then, owing to the scarcity of laborers, and ill health on my own part, those crops were all and more than I could attend to properly. The season was favorable to the growth of potatoes, corn, and—weeds. If I could keep down the weeds I knew that corn and potatoes would yield me something, while the bees did not promise any thing, as it appeared that clover would not blossom at all. Should I peg away at a certainty, save my other crops, and let the doubtful bees go? I did that very thing, so far as I was able. I knew most of them would get along, although poorly. Some were in a starving

condition; all were listless and inactive. The busy roar of a honey season was never heard last summer. Twice I looked, to find a colony starving, and fed them up. Two weak ones died. I raised one batch of cells, but several queens never hatched.

But I will not detail all the losses from pure neglect. The middle of August found the prospect as bad as ever. About that time I undertook a job at which I knew I could make wages. It assumed larger proportions than I thought it would, and in the midst of it the biggest flow from heart's-ease I have ever known, with perhaps one exception, set in. I seldom get any surplus from fall flowers, when the hives are already nearly full. I have been so often disappointed that I had ceased to look for any thing from those sources. Now, when a boom had come, my bees were not in a condition to take advantage of it. Very few of them would go into surplus arrangements, and many were too weak to carry much into the hive at all. By dint of hard work I think I saved about all the bees could gather. I realized only about 400 lbs., comb and extracted. All the latter was taken from the brood-chamber; and when I came to prepare the bees for winter, quite a number of colonies were so weak that I had to unite them, and some others were weaker than I generally put into winter quarters. I have not half the extra combs in the honey-house that I shall need to feed them next spring, if the season is the most favorable. My stock has run down—in spite of a few swarms—lower than it has been for five years—nine colonies lower than a year ago.

Now, have I made or lost? Have I done right or wrong? Is it best to get my eggs in more than one basket, and thus have too many irons in the fire? I believe I have done the best thing under the circumstances. I have lost in bee-stock, and made a living. The loss will be felt in the future, that I may have my victuals and clothes in the present. If I could live without eating, and go barefoot, I should be that much better off. But bread and boots are necessities, and I must have them, even at the expense of capital for future use. For me, then, situated as I am, it is better to have more than the one resource (bees), even though that resource sometimes suffers by it. But if my situation were better—if I had a little surplus to help me live for a season, it would be better for me to stick to my bees through thick and thin. I should certainly be better satisfied, for I like bee-keeping better than any other occupation I have ever tried.

ARE QUEENS INJURED IN SHIPPING? A TESTIMONY.

On page 22 Mr. Swinson revives that subject. When I read Mr. Doolittle's article, page 749, 1888, I thought, "That accounts for it." I bought an imported queen of A. I. Root, in the summer of 1886. She was still living and laying this fall; but never, since I have had her, has she approached the average as a layer. In that respect she has been a perpetual disappointment to me. I knew not what to make of it until I read the article referred to.

GEO. F. ROBBINS.

Mechanicsburg, Ill., Jan. 10, 1889.

Friend R., I do not believe that you would be any happier than you are now, if you could live without eating, and go barefoot, as you express it. I think it is well to have more than one resource for a livelihood; but at the same time it behooves us to watch keenly, so as to be sure to make the best of both or all of our resources.—I

do not quite like your reasoning in regard to that imported queen. You have good proof, it is true, that imported queens are, some of them, poor layers, like all other queens; but certainly the single instance you mention does not go very far toward proving that *all* queens that have crossed the ocean are necessarily less prolific than others. I believe that reports have been given on these very pages, of queens that crossed the ocean, and afterward took long trips by mail, and yet furnished quantities of brood that would compare with any home-reared queen. Nearly half of the colonies in our apiary are provided with imported mothers; and, as a rule, we have been in the habit of expecting a little *more* of them in the way of egg-laying, rather than less. Their journey across the ocean certainly does not permanently cripple them.

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

SOMETHING IN REGARD TO BUSH LIMA BEANS IN GENERAL, FROM PETER HENDERSON.

MR. ROOT:—I notice your continued efforts to get at the facts about the new Bush lima, that have been questioned by two or three of our disappointed contemporaries who feel annoyed about not being fortunate enough to get hold of such a good thing. That is human nature, and I must admit that I would have felt any thing but pleasant had we been left behind in such an important race, particularly if we had had the thing first in hand and failed to see its merits, as one of your correspondents admitted to me he had. Still, had such been our misfortune I hardly think we should have been weak enough to show our chagrin by decrying it when it was being sent out by a rival firm.

I notice what you say about having our Bush lima cooked and tasted by your family, and that you thought it had not got the lima flavor as much as the pole limas. I am afraid you are in error about that. We made a complete and exhaustive test of it the other day. We had them mashed up so that the size of the beans could not be seen, so as to influence judgment. We numbered the samples, sent half a dozen of our clerks as tasters, and the universal judgment was that there was no perceptible difference, because dried limas of *any* kind give but little of the rich *lima* flavor.

Now, I will give some of our contemporaries, who are claiming to have the large lima in bush form, a chance. I will pay one thousand dollars for a single bushel, or seven cents each for 15,000 beans, on proof that the seed will produce the *large* lima in bush form, as is done by our new bush lima. That it will yet be done is probable, for there is no reason that the large lima should not "sport" to the bush form as the small lima has done.

One of our near neighbors, William Elliott, one of New York's well-known seedsmen, was sent about a bushel and a half of large limas last fall, with a dried specimen of the plant, which certainly showed it in that condition to be a bush lima. I offered him nearly \$1000 for his bargain (?), but he laughed me to scorn, for he thought there were many thousands in it. But, alas! "the best-laid schemes of mice and men gae aft a'gae." Mr. Elliott's "dwarf"

beans, all of them on trial, got to the top of the highest poles. Somebody had "pinched back" the pole lima to throw it into bush form, and sold, or *tried* to sell, Mr. Elliott the product, because I believe he was sharp enough not to pay for the seed until it had been tested.

PETER HENDERSON.

New York, April, 1889.

Many thanks, friend Henderson, for kindly posting us in regard to this matter. I am very glad indeed to see your offer for a Bush lima that will furnish beans as large as our pole lima beans. It seems to me that this whole matter begins to look as if it might usher in a new era. What I mean is this: We have for years been breeding cattle, horses, poultry, etc., to supply the demands of the market; and almost as soon as it begins to be evident that there is a demand for a different animal from what we have already on hand, straightway somebody brings it out.

Now, friend Henderson has, in the above, told us just what he wants in the way of a lima bean, and I am exceedingly glad to hear him say he is ready to pay one thousand dollars for it. I am much better pleased to have such an offer as this than I should be if somebody would offer a thousand dollars for the best newspaper story, because I think there is much greater need of having boys and girls out in the open air, developing nature's treasures—yes, raising beans if you choose—than there is to have them crowd our newspapers and periodicals with rejected manuscript. The concluding sentence from Peter Henderson reminds us that swindlers are already in the business, and that we should look out before we pay out our money. And this brings us to a consideration of the Kumerle lima bean, offered by Thorburn. I do not believe that this is a humbug, because Thorburn's name itself is a sufficient guarantee, only I wish he would tell us more about it. Has Thorburn himself ever grown the bean itself, or seen it growing?

Here is something in regard to Kumerle's Dwarf lima bean, from another seedsman:

Mr. Root:—I am acquainted, in a business way, with the originator of Kumerle's Dwarf lima bean, who supplied Thorburn & Co. He says, "It is a sport from Dreer's improved lima bean, possessing all the fine qualities of the parent; grows two feet high, branches out in all directions, and should be planted in good soil, in rows three feet apart. It does not require any poles. It has been grown for three years, and has shown no tendency to run." He sold it this season only in packets containing 13 beans, at 25 cents. I have one packet. I have written him, and asked him to set a price on 100, 500, or 1000 beans; and if they can be got I will get his permission to send you some for trial.

ISAAC F. TILLINGHAST.

La Plume, Pa., April 4, 1889.

As we go to press we have nothing more from friend Tillinghast, but hope to have something favorable soon.

Here is a report from the Henderson Bush lima, right near where it originated:

HENDERSON'S BUSH LIMA BEAN.

For two seasons past I have cultivated the Bush lima bean. Having a wet season last year we found

it necessary to place brush close to the plants on each side of the rows, to keep the pods from touching the wet earth, which speedily rotted them. The beans are as large as the old Carolina or Sewee lima. I obtained them of a party in Prince Edward Co., Va., where it seems they have been known for several years. During the last six years I have grown an onion that corresponds exactly to the description given in the catalogue, of the so-called New Egyptian. To my certain knowledge it has been raised in Virginia for the last 20 years. A. S. MARTIN.

Roanoke, Va., March 13, 1889.

Thank you, friend M. We should be exceedingly obliged for any facts you can give on the subject of the new lima beans. It is quite likely that the onion you mention is the New Egyptian. I have heard of it from several localities, although it seems that Gregory was the first to catalogue it and bring it generally before the public.

THE CATALPA; IS IT A DESIRABLE TREE FOR ORNAMENTAL PURPOSES?

Some nurserymen are advertising the *catalpa* as a very hardy and desirable tree for ornamental planting. They state that plants the size of straws, planted late in May, grow to be seven feet high, and four or five inches in circumference, at the base. Please tell us if it is grown in your locality; and if so, with what success. ROBT. H. SHIPMAN.

Cannington, Ont., Can., Feb. 18, 1889.

Friend S., in California the *catalpa* does all you mention; and I am inclined to think that it does even more; and, best of all, when it is once started it will live right through the long drouths, without any irrigation at all. It grows in our locality, and makes a very rapid growth—I think not much more rapid, however, than the soft maples that adorn the streets of Medina, and we think the maple the handsomer tree. The *catalpa* yields considerable honey some seasons, but it comes exactly at the time of the basswood flow, so that our bees seldom pay much attention to it.

KEEPING CELERY-PLANTS FROM RUNNING TO SEED IN THE SEED-BED.

If you don't want your celery-plants to go to seed, don't let them ask twice for a drink, at any stage of growth. M. GARRAHAN.

Kingston, Pa., Feb. 24, 1889.

I am well aware, friend G., that the weather has a great deal to do with successful celery culture; but I hardly think that lack of water explains all the difficulty. Almost every year when our celery-plants stand in rows in the field, while cultivating we find occasionally a stalk running up to seed. These are pulled out as fast as noticed. After a certain stage we see no more of it. It may be our Golden Dwarf celery that started to run to seed in the seed-bed did so on account of lack of moisture, at a critical time. I am inclined to think that this is the case, for at one time it seemed as if they were all going to seed. After I pulled out these and threw them away there was no more of it during the season. Perhaps the abundant rains accounted for the latter fact.

MEL SAPIT NIA.

JOTTINGS FROM AMATEUR EXPERT, OF ENGLAND.

WE have been holding the annual meeting of the B. B. K. A. at Jermyn Street, London, during the past few days, so I thought I would send you a few particulars. Hitherto no one has been eligible for election on the managing committee unless he subscribed 10 shillings per annum. Each member was entitled to one vote for every 5 shillings subscribed, and a life member by paying £5 down was entitled to 4 votes per annum as long as he (or she) lived. This may seem strange rules to you, and I will not go into the why and wherefore, but pass on with the remark that these rules are common to similar societies in England. For three years we have tried to alter this, and, inch by inch, we are fighting the ground. This year we have carried the point that all and any members are eligible for election on the committee, whether they subscribe 5 shillings or more. The one-man one vote we could not carry, the rich subscribers having outvoted us. But we shall sharpen our swords for another year, and renew the conflict. I may say all this is done without party feeling; we manage to fight these battles and not lose our tempers.

Manufacturers of and dealers in bee-appliances are not eligible to act on the committee. How would that suit you? Hitherto we have kept them off by not voting for them, but now they must not be nominated. I protested strongly against such a rule being made, but it was, as the majority was strong for it.

County associations affiliated to the B. B. K. A. have hitherto sent a representative each to the quarterly meetings of the B. B. K. A., but these representatives have had no vote, and could only make suggestions, which the committee of the B. B. K. A. could please themselves about carrying out. We have now made these county representatives *ex-officio* members of the committee of the B. B. K. A., with full voting powers. I have enumerated these points as you have recently been altering the constitution of your N. A. B. K. A., and I thought they might interest some at least of your readers. There were several other matters considered at the business meeting, after which we had a "conversation," and Mr. Cowan, who came over from Switzerland to attend, read a paper on

THE BEST HIVE.

Of course, he was in favor of the hive he has so long used, which bears his name, and is known as the "Cowan" hive. It certainly is the best for our climate and circumstances; but as I may say something about hives on a future occasion, I will pass on, to say the discussion that followed was most interesting. It is seldom that we get a subject so rudimentary for discussion as this; and for myself I am pleased that Mr. Cowan brought it on. Our usual bill of fare is some abstract theory or scientific problem that has some remote bearing on bee-keeping, while practical bee-keeping is left out in the cold to shiver, on such occasions.

WINTER AT LAST.

During the past month we have had a few cold spells, with snow and sharp frosts. In the day time on clear days the sun has shown out very warm, and drawn out the bees for a fly. Stores are getting very low in some of our hives, and breeding

has been carried on all winter, I believe, in many of them. Many scores of colonies kept by the poor are dying. One old lady, who is over 75 years old, and has kept bees all her life, and her mother and grandmother before her, cried to me last week as she told me all her bees were dead, and she had never known such a thing as to be without bees, all her life. She felt "quite lonely," she said. I fear many will be in the same position before June 1st, as bees went into winter quarters so very short of stores.

LADY BEE-KEEPERS AND WRITERS.

We are getting an exchange of bee-writers, it seems. Mrs. L. Harrison is to write for the *B. B. J.* monthly, Mr. Cowan tells us. Her name seems so familiar to us all on this side that she is counted one of us, and does not come at all in the guise of a stranger. We have several very successful lady bee-keepers in England. I beg pardon—I mean the United Kingdom. I must not forget that, especially as one from the Emerald Isle has recently sent me a most flattering invitation to pay her a visit. Would you like to hear something about our lady bee-keepers? If so, I must get their consent and go on a "ramble" and tell you what I may see while on my rounds. I must first ask permission, though; it is rare fun sometimes, let me tell you, when I go to see my bee-keeping friends. They will first say, "Well! is it A. E.?" If I say, "No, only Mr. S—," (ah! you thought I was going to write it, did you?) they then know what is said is sacred; but if I, on the contrary, say, "You had better beware," then they are sure to look keenly in the bee-papers. But our lady bee-keepers, allow me to say, are not like yours. It is not that they are more modest—the bare suggestion would rouse a storm about my ears among your ladies—but until very recently, at least, it has been the fashion for our women to be kept out of any thing that savors of publicity, and our customs are so deep-rooted that very few indeed can be induced to step out into the arena of criticism and tell us what they know about bees, much less about themselves in any other sphere. In

MRS. CHADDOCK

you have a contributor who is unique; her easy, original style of dealing with personal matters is very charming to English readers who are not over-fastidious about conventionalities. But her courage in fighting the "professors" and some of their wild theories about evolution is especially charming to many of us who know how to rightly estimate much of what has been written in the name of science.

A BEAR-STORY.

I wonder how the grizzly bear knows where to find honey, and whether he is led by color or scent. Talking about bears and honey reminds me about a tale I heard the other day from Central Asia. It having been observed that several of the telegraph poles were dug up, a watch was set to catch the depredator, when it was found to be the work of a bear. This led to an inquiry as to the reason for the bear wishing to lay the telegraph poles to the ground. They were iron poles, and he could not climb them; and hearing the humming noise made by the wind in the glass insulators, it is supposed he imagined there was a bees' nest on the top of the pole, and so he dug the pole down to get at the honey. Perhaps Mrs. Chaddock can say if that was instinct or reason.

THOSE BIOGRAPHIES.

Well, before I close I wish to tell you how we like your bee-keepers' biographies by Dr. Miller. It is very interesting to read about all those whom we have known so long by name. The portraits make it doubly so. I was showing them to a friend the other day, and when he came to the editor of GLEANINGS he laughed aloud. On asking what was the cause, he said, "What a dunce I am! I see now his name is Amos Ives Root. I always thought he styled himself A. I. because he was a kind of 'double first,' just as the best steamships are classed 'A I' at Lloyd's shipping agency," and so he laughed again at his own folly, and said, "But he is A. I., for all that." AMATEUR EXPERT.

England, Feb. 25, 1889.

Friend E., your bear-story is a very good one—very ingenious the story is, whether it be true or only fiction. And so you have telegraph-poles made of iron, do you? That is something I never knew before. And so some of the friends across the water thought A. I. Root was vain enough of himself to call himself "A I." Why, the very thought of it gives me pain. I feel glad and proud of being one of the people—one of the great mass of humanity; but I never wish to be considered anywhere or by anybody any thing more than the commonplace individual which I am. If I thought it possible that anybody else might think so, I don't know but that I should write out my full name every time—Amos Ives Root. Thanks for your friend's concluding remark.

A. E. MANUM.

THE MAN WHO OWNS 700 COLONIES IN 8 APIARIES,
AND WHO IN 1885 PRODUCED 22 TONS OF
HONEY.

AUGUSTIN E. MANUM, whose picture is herewith presented, was born in Waitsfield, Vermont, March 18, 1839, consequently he was fifty years old March 18, 1889. When Mr.

Manum was nine years of age his father died, leaving him only the inheritance of a sound mind in a sound body. At an early age he apprenticed himself to a harness-maker, and afterward continued in the business in the village of Bristol, Vermont, where his home now is, until he abandoned it for the bee-business. In 1859 he married Miss Rosilla M. Pierce, the beloved wife and kind mother whose death a short time since casts a shade of sadness over the home.

When the war broke out he enlisted in Co. G, 14th Vermont regiment, as a nine-months' man. He served at the battle of Gettysburg, where his comrades in line on either side were killed; his own gun was shattered, and he was hit four times.

In March, 1870, a friend desired to lend him "Quinby's Mysteries of Bee-keeping." Reading the book, his enthusiasm upon the subject was kindled, and he immediately purchased four colonies of bees and began the study of apiculture. Having a natural aptitude for the business, and a love for the bees, he was successful from the first. His apiary so rapidly increased, that, at the end of four years, when he had 165 colonies, he sold out his harness-business and began the pursuit as a specialist. At this time he was using a 4-lb. honey-box. Soon came a demand for a smaller package; and as sup-

ply-dealers were scarce, he determined to manufacture them himself. In casting about him for seasoned lumber of a proper thickness, he found, to his great delight, a quantity of poplar plank. The result was a lot of poplar sections, the first ever made. Mr. A. I. Root was much pleased with a sample sent him, and published a description of them at the time in GLEANINGS. This notice brought in inquiries and orders by the score, and Manum the bee-keeper became Manum the supply-dealer. His first order for sections from out of the State was from Mr. L. W. Baldwin, of Missouri, at \$11.00 per 1000. Soon the demand for these sections became so great as to call for a more rapid method of manufacture; and Mr. M., having purchased a mill with abundant water-power, invented a machine working automatically, which sawed the sections accurately and so smoothly that many im-

A. E. MANUM.

plained them sandpapered. The supply-business and the bee-business soon grew to such proportions that it was impossible to personally manage both, and the factory was, in 1884, sold to the present proprietors, Messrs. Drake & Smith. Since this time Mr. Manum has devoted all his energies to the production of comb honey, increasing his plant until his bees now number over 700 colonies in eight apiaries. He always winters his bees out of doors, packed in the "Bristol" chaff hive. For the eight years previous to 1887, his average loss in wintering for the entire time was only $3\frac{1}{2}$ per cent. He uses exclusively a frame about $12\frac{1}{4}$ x 10 inches, outside measure, which he considers the best for practical purposes in his apiaries. His hive, the "Bristol," is almost entirely his own invention, being specially adapted to the perfect working of the system upon which his bees are managed. In 1885 his production was 44,000 lbs. of comb honey, an average of 93 $\frac{3}{4}$ lbs. per colony, all made in twelve days from basswood.

Because of the failure of the honey sources the past season, about 14,000 lbs. of sugar syrup was

fed the bees to prepare them for winter. He still has much faith in the pursuit, although the past three successive poor honey years have told heavily upon his enthusiasm.

Mr. Manum has one son, a fine young man, just of age, who promises soon to be a great relief to the father in the management of his extensive apiaries.

Mr. M. is of medium height, with dark complexion, hair, and eyes. A kind friend, an upright gentleman, and a thorough business man, he has attained an enviable position among the bee-keepers of Vermont, where he is so universally known. His extensive operations, his uniform success, and his practical writings, have also given him a national reputation.

J. H. LARRABEE.

Larrabee's Pt., Vt.

Friend L., I well remember when Manum's samples of Vermont white poplar came into our office. We had been for some time making sections then ourselves. This white poplar "took the shine" off from any thing in the line of basswood so completely that at first I was inclined to feel a little bit jealous; but it did not take me long to decide that I would tell our readers the truth about it, no matter how much it hurt our trade. I do not remember the exact words of the editorial, but it was to the effect that friend Manum's white poplar was nicer than any thing we had ever made, and, I believe I added, nicer than any thing we could *hope* to make, unless we could get that same white poplar. In a little circular that came along with the sections, the printers had put it "popular" instead of *poplar*, and there was no little merriment about friend Manum's white "popular" sections; and indeed they *were* "popular" after my editorial went out. Years passed; and while attending the National Convention in Detroit, a large fine-looking man came up and put out his hand, and said it was a pity that, after all these years, he too could not have the pleasure of shaking hands with his benefactor. I asked him what he meant by "benefactor." "Why," said he, "Bro. Root, I am the man who made those white-poplar sections to which you gave such a boom by your kind editorial; and now I want to say to you, that, although I have not yet amounted to *very* much, what little I have done I owe greatly to that kind and disinterested editorial." And then there was a big laugh all round. When I wrote it I had no acquaintance whatever with friend M. I only knew that the beautiful smooth pieces of wood that almost rivaled white paper in whiteness were, both in workmanship and the quality of the wood, beyond any thing I had ever seen before. White poplar, from its nature, is not suitable for one-piece sections, therefore they must always be made in four pieces; and as the material is somewhat scarce it is not likely they will ever be furnished for much less than double the price of the basswood sections. The bee-keeping world, however, owe a debt of gratitude to friend Manum for furnishing the finest section, so far as I know, that has ever been made anywhere. Dr. Tinker, I believe, finds on the hills in his vicinity a kind of white poplar

that very nearly equals the Vermont poplar. It may be well to say, also, that, if the doctor's sections are lacking any in quality of material, they excel in *workmanship*, perhaps, any thing the world has yet produced.

BEE-FEEDERS.

FRIEND HEDDON'S COMMENTS ON SOME THINGS IN MARCH 15TH ISSUE.

NOTICE on page 216, in an illustration and translation from a French bee-journal, something regarding feeders. Now, while I have had considerable experience with feeders, both in feeding bees large quantities for wintering and feeding back extracted honey to finish thousands of pounds of sections, I wish to say to your readers that I found a feeder based on the principle of the one shown in the cut as in many ways unfitted to the instincts of the bee. In the first place, the two little feed-troughs do not afford sufficient space for the average colony of bees to do the rapid work required. Then there is no need of the wood feeder being lined with metal. Not one in twenty, if properly made of wood, when constructed as they should be, will leak; and if one does leak it will not leak outside the hive, but all within, where the few drops will be picked up by the bees and no robbing be incited. The only valuable principle I discover about this feeder is the reservoir plan, wherein the bees rise up, rounding over a lowered partition, taking the honey from the top, the reservoir keeping the feeding-troughs full, by force of gravity, the same as the stand-pipe waterworks system. Let me say to your readers, that it was not only "several years ago," but a good many years ago, that I discovered this principle. While I know it was original with me, I do not know whether it was prior or not. I think it was, for, so far as I have been able to discover, there is nothing in print touching any of the principles until after I had used it for several years, and also, I believe, described it in bee-journals. With this communication I inclose you an engraving and description of the feeder, and on the second page is clearly outlined what I claim as my invention, whether prior or not, not patented, I want you to understand. After reading it, you will say in your foot-notes what you believe concerning it.

UNPAINTED HIVES.

About fifteen years ago the same idea entered my mind in regard to painting hives, which I find in the article of G. M. Doolittle's, beginning on page 217. Upon the strength of my new supposition I made between thirty and forty hives, leaving them unpainted, and used them for several years, carefully noting results. I had lost quite a per cent of my bees with the winter disease known as bee-diar-rhea (the only winter difficulty, in my mind, worthy of mention). While I found, by actual experiment, that omitting the paint allowed the hives to become so dark in color that they drew the sun's rays, piling up the heat, making them very objectionable in hot weather in summer, and that the rain, so far as it could get at them, had caused them to become rotted at the joints, I found no difference whatever in regard to the successful wintering of my bees. It is to me another of the fine-looking theories which have to vamoose before experience. It appeared to my mind, before it re-

ceived my more careful attention and experiments, the same as it does to Mr. Doolittle's. In your foot-notes you mention the success of the chaff hive. Let me ask you to make this experiment: Take a colony of bees that you have managed all summer in Simplicity hives, along late in October, about a week or so before the bees cease to fly, and set them over into a chaff hive, and see how they winter then, after that disturbance. I have repeatedly noticed, that, when a hive is thus disturbed, especially after the brood-frames are opened and the combs interchanged, late in the season, these bees will not winter so well as those not disturbed. This says to me, "Pack your bees early." I presume you remember that I am radically an anti-chaff, or tenement-hive, bee-keeper. During summer management, all my hives must be very light and most readily movable, for I propose to work two hives with the same expenditure of time and muscle that is usually applied to one.

YOUR DOVETAILED HIVE.

Under this head, on page 234 I am pleased to learn that you will use the honey-board single bee-space, leaving it flat on one side, and the bee-space in the brood-chamber at the top; and in order to make this brood-chamber and the surplus receptacles readily interchangeable, you have made a bottom-board with a bee-space in that. That is exactly like my new hive. That is just what I did, as you will see by the cut I inclose. You will also notice the style of cleats I nailed on, which style furnishes a more solid base, and gives a narrow bearing to avoid crushing the bees. Now, if you had your brood-chamber in two sections, each containing a complete set of shallow frames, with side frames tightly fitting the case, but reversible at will, you would just have my new patented hive, if made and used as and for the purposes specified. I fear, friend Root, that your investigations and reasonings concerning hives will end up as it did with the honey-board. You will first oppose, then tolerate, and finally embrace the new hive in question.

Dowagiac, Mich., Mar. 22, 1889. JAMES HEDDON.

Thanks, friend H. Your first objection to the Miller-Warner feeder (i. e., if you included it with the one illustrated on page 216 of last issue) with us does not hold true in practice. We fed several barrels of syrup last fall, and, as a general rule, the bees emptied the feeders in a single night, no matter whether the feeders contained 5 pounds or 25 pounds of syrup. In some instances we filled the feeders entirely full (a capacity of 30 pounds) all of which was taken down and deposited in the cells in less than 12 hours. Is not this rapid enough feeding for all practical purposes? It is true, as you say, there is no need of lining such a feeder with tin; but if you will refer to our descriptive remarks, and to the engraving on page 818, for 1888, you will see that the feeder we manufacture is made entirely of wood. The great point we urge in favor of the Miller feeder is, that the passageway affording access to the feed is located directly over the center of the brood-nest, and this passageway is closed at the top by a board, so as to confine the heat. Accordingly feeding can be done in cold weather comparatively. That this is not mere theory, is evidenced by the fact that we have had colonies, by way of experiment,

empty these feeders, during freezing weather, in chaff hives.—As to the Dovetailed hive, we are pleased that you like the change which we have made in the matter of the bee-space. We did not take the idea of putting the bee-space on the bottom-board by means of cleats, from your new hive. We suppose you know it is an old idea. Years ago, before we adopted the bevel on the Simplicity hive, we used such a bottom-board.—In addition to what Ernest says, I will add I objected to such a bottom-board then and do now, because, if made in that way, the bottom-board and cover will not be exactly alike. The simple features of the Simplicity hive are, that there are only two pieces or two things to the hive—a body and a cover. The body is an upper story or a lower one, as you choose; and the cover is a bottom-board or a cover as you choose. When you have a stock of one you have a stock of the other.

THE UNITED STATES HONEY-PRODUCERS' EXCHANGE.

THE BENEFITS OF THE STATISTICS.

THE above association was organized under the auspices of the New York State Bee-Keepers' Association, in convention at Utica, N. Y., Jan. 17, 18, and 19, 1888. Its object is to furnish to its members prompt and reliable information as to the honey crop throughout the United States. Six or more reporters are appointed in every honey-producing State, who forward their reports to the Secretary on the first day of May, June, July, August, and September. The Secretary compiles these reports from each State (separately), and on the 10th of the month forwards to each member of the "Exchange" the reports from the whole United States. These statistics embrace the increased or diminished number of swarms going into winter quarters, loss in winter and spring, condition of bees at beginning of season, proportion of full crop of honey gathered, both white and dark, comb and extracted, the quantity of honey in the different markets remaining unsold, with price, etc.

The advantage of this information is too apparent to require any elaboration here. We would only say, that if you know the honey crop the market is yours, and you can secure prices in keeping with the amount of honey which you know is on the market. The "Exchange" has met with great favor among bee-keepers, several members present at Syracuse (Dec. 11–13), and others from abroad, among whom are many of the largest honey-producers in the United States, stated that the information furnished by the reports during the past season had been worth many dollars to them in the disposal of their honey, while other prominent bee-keepers pronounced it the best thing that ever came from an association of bee-men. Feeling assured that you will wish to reap your share of the benefits of these statistics, we extend a cordial invitation to you to join the "Exchange" by forwarding your membership fee to the Secretary, G. H. Knickerbocker, Pine Plains, N. Y., which will entitle you to the reports for one year; and also, if you can attend its meetings, to all the advantages of membership in the New York State Bee-Keepers'

Association, without further expense. The fee is one dollar per year, but it is hoped that enough bee-keepers will join so that the dollar will cover the cost of two years' reports, in which case you will receive the same for that length of time. Three or four hundred new members are yet needed to bring about this result. Each member will also receive, with the report sent out May 10th, a list giving the names and address of all the members and reporters. These statistics will not be furnished to the journals for publication, but will be sent to members only. We could not meet our expenses were we to make public our reports.

The "Exchange" has the indorsement and support of such well-known men as Dr. Miller, Dadant, Grimm, Manum, Crane, Cushman, Vandervort, Mason, Tinker, Pond, Cary, Root, Hetherington, Cook, Martin, Barber, Isham, Doolittle, Clark, Aspinwall, Van Deusen, Heddon, Taylor, Hilton, Cutting, Valentine, Demaree, Shuck, Foster, Secor, Wilkins, Muth-Rasmussen, and others equally well known.

P. H. ELWOOD, *Pres.*,
I. L. SCOTFIELD, *Vice-Pres.*,
C. G. DICKINSON, *Treas.*,
G. H. KNICKERBOCKER, *Sec.*

We gladly give place to the above, and hope the bee-keepers will not be slow to give it their indorsement by way of subscriptions.

CAPT. HETHERINGTON

AS A BEE-KEEPER AND AS A SOLDIER.

CAPT. HETHERINGTON was one of the founders of the Northeastern Bee-Keepers' Association (now the New York State Association), one of the oldest if not the oldest organization of its kind in the country, and, after the death of Mr. Quinby, its president. He was also present at the organization of the National society, and, later, elected president, but declined this honor on account of poor health. At one time he was associated with Mr. Quinby in giving addresses on bee-keeping before farmers' clubs in some of the principal towns of Central New York. He has a good command of language, and is a clear, forcible writer and speaker; and it is to be regretted that time and strength do not permit him to make a more free use of his gifts in this direction.

Socially, and as a host, he has no superior and very few equals in the fraternity; and many who read this will testify to the excellent treatment received at the hands of himself and his accomplished wife. The captain enjoys his home life and associations better than the most of men; and while he takes great pleasure in entertaining his bee-keeping friends, he does not always feel reconciled in having the privacy of his home invaded by the professional tramp, who, as soon as he purchases a swarm of bees, must hie away to the most celebrated authority for instruction instead of consulting some A B C book of bee culture, written for his benefit. Of late years Capt. Hetherington has sought to remain unknown, and to avoid notoriety; not, as he says, because he has nothing to communicate, but because it was necessary to economize in time and strength.

The captain is a regular attendant of the Presbyterian church, of which his wife is a member. He is also an officer and worker in the Sunday-school, which his three children, two boys and a girl, at-

tend. He likes a religion of a practical, working kind, that bears immediate fruit; that raises the fallen, feeds the hungry, cares for the sick. At the same time he believes there is a divine side to religion, with duties beyond those to our fellow-man, and with privileges and enjoyments and helps not found elsewhere. Capt. H. is an active temperance worker, and has been for many years a member of the Good Templar order. He also ranks well up in the Masonic order, and has been several times Master of Cherry Valley Lodge.

We must not fail to mention his splendid military record. October 12, 1861, he enlisted in Company D, 1st Regiment U. S. Sharpshooters, Col. Berdan commanding. It was from no boyish freak, but from a deliberate sense of duty, that he left the then most extensive bee-business in the land, and entered the service of his country. The spare time of the summer before had been spent in target-rifle practice, and his mother had made his underclothing previous to enlistment. But war is an easy thing to write about, but a terrible thing to deal with. Before one year had expired, of nine intimate friends from Cherry Valley who had entered the army, four were dead, four discharged for disability, and Captain Hetherington alone remained in the service. General Sheridan says, "Courage measures the power the mind has over the body." The captain stood at his post in a most dangerous branch of the service, when most men would have been in the hospital, or discharged for disability. His army surgeon has left on record the following tribute to his bravery: "On the 12th day of May, 1864, at Spottsylvania, he became very much exhausted by reason of chronic diarrhea, but declined being relieved from duty; and although wounded in the head he heroically remained in command of his company." And again, "On the 22d day of June, 1864, in action before Petersburg, Va., he received a serious wound in the hand, which disabled him from duty. At the time of receiving said wound he was suffering from chronic diarrhea, and was so weak and debilitated by it that he was a better subject for the hospital than the battlefield." This was the wound received when his sword was shattered by a bullet, and a piece of the weapon was driven through his hand. The engraving shows this piece lying by the broken sword.

THE SWORD WHICH SAVED THE CAPTAIN'S LIFE.

The portrait shows the position of the sword and hand. He had for the moment thrown his rubber blanket* across the hilt of his sword, and that over his shoulder, very much as a tramp would carry

*Before an engagement, an officer transfers to his darkey or servant all luggage—retaining only his rubber blanket and haversack, for use in case the aforesaid gentleman fails to put in an appearance after the fight. His blanket is made into a small roll and tied at the ends, then carried across his shoulder and breast as a sash is worn. In hot weather this is oppressive; and for temporary relief, although in the midst of a hard fight, the captain had thrown his rubber across the hilt of his sword, and that across his shoulder.

his pack. Providentially the bullet, so well directed, found a lodgment in his sword and hand instead of his heart, which, you notice, lay just beneath. Major General Wilkenon, of the British Army, on seeing this sword, said that he had seen many of the heirlooms of prominent British families, and the relics sent home from twenty years of active service, and added, "Among them all there are none that I consider as fine a personal relic as this broken sword." The captain threw this away as being of no further use to him; but it was preserved by his men. He also received a gunshot wound in the shoulder, in the second battle of Bull Run, Aug. 29, 1862. Entering the service a private, he came out a captain, in that division of the army when a captaincy meant [in some ways as

CAPTAIN HETHERINGTON DURING WAR TIMES;
THE POSITION OF HAND AND SWORD WHEN
STRUCK BY THE BULLET.

much as the command of a whole regiment would in some other branches of the service. A whole regiment of sharpshooters was seldom posted together; but companies were used instead of regiments. The sharpshooting service was a man-to-man conflict, and it required great care and skill in posting a company so that they would not be picked off by the opposing riflemen. The captain of Company D was killed in the battle of Gettysburg, July 3, 1863, and Lieut. J. E. Hetherington was recommended for promotion by Col. Berdan, from the battle-field. At the close of the Gettysburg campaign, an order was sent to the commanding officers of the army, to report to the Secretary of War the names of such officers and men as had distinguished themselves for bravery and meritori-

ous conduct during the campaign. The name of J. E. Hetherington appears in this list, and furnishes the best of proof that his promotion was well earned. While in the army the captain was in all the principal battles of the Army of the Potomac, besides many minor engagements which will never be recorded. He was discharged from the service, Sept. 20, 1864, by reason of disability from wounds received in action. For two years after, it was a question whether he would live; but he gradually regained a larger part of his former vigor.

In personal appearance the captain is tall and commanding, and looks every inch a soldier. Had our army been more largely composed of such men, the end would have come sooner, and general pension bills would not now languish. With more years, undoubtedly higher rank and greater honors had come to him. The bee-keepers of this country may feel honored that they have enrolled in their ranks one who has performed so distinguished service in the great contest.

Starkville, N. Y.

P. H. ELWOOD.

It was my good fortune to meet Captain Hetherington at a bee-keepers' convention in Cleveland, O., in December, 1871. This was only one year after the National Convention was started, and the bee-men of the United States were, a good many of them, comparatively slightly acquainted with each other. The only time I ever met father Quinby in person was at this convention. I believe it was the first time I got acquainted with Prof. Cook. A. F. Moon was there; also W. F. Clarke, Dr. Bohrer, Dr. Hamlin, Aaron Benedict, Gen. D. L. Adair, N. C. Mitchell, Mrs. Tupper, Mrs. Savery, and R. C. Otis. Rev. L. L. Langstroth was absent on account of illness, and so W. F. Clarke occupied the chair. The memories of that convention are very pleasant. Although there were a few things that marred the harmony, yet there were but a few. H. A. King and R. C. Otis were at that time having trouble about the Langstroth patent. Among the exhibits of bee-hives, Otis brought in an old weather-stained American hive, and in an ironical way commenced to extol its merits. As a matter of course, a part of the convention decided with Otis and a part with King, and there seemed to be great danger, for a time, of hard feelings if not hard words during the session of the convention. The president, however, happily suggested that we close the session by singing the doxology. The effect of that simple hymn of praise acted so like oil on troubled waters that I never quite got over it. I was not a Christian at the time, but I then got a glimpse of the power of Christianity to subdue and conquer evil. I did not have a chance to get much acquainted with Captain Hetherington. I can only remember that, when the essays were very long and dry, as you may remember they used to be, he acted somewhat like a schoolboy under restraint; and, if I mistake not, he once started a little fun, even during the reading of these essays. If we could get him to attend the conventions of the present time he would find a vast change in them from what they were 18 years ago.

HEADS OF GRAIN FROM DIFFERENT FIELDS.

DO WE NOT MANIPULATE OUR BEES TOO MUCH?

MY experience is, that most of us spend too much unnecessary labor on our bees. My plan of late years has been to have small hives, 7 and 8 combed L. and 8-combed Gallup (I use both kinds). Just as soon as the hives are full of bees I put on one crate of sections and let them swarm naturally. I have plenty of hives ready, and when I do not care for increase I double up two swarms to each hive, hiving them on two crates of sections, with metal queen-excluding board between the lower hive, filled with frames of foundation. In this way I always have good young queens in my old colonies, with plenty of stores for winter. Bee-keeping at the present low price of honey is like farming in the West—we must save all the labor possible. When I first moved to Kansas, some years back, I thought our Eastern mode of farming would do there; but I soon found it was money out. I soon changed, and followed the farming of the country—at least, such as those followed who made a success of it. So it is with bee-keeping—each section of country has to be learned, and then they must be run to suit.

T. G. ASHMEAD.

Williamson, N. Y.

Friend A., perhaps almost all of us perform unnecessary labor with our bees; and I have sometimes thought a great deal of hard laborious drudgery is constantly being done when there is no reason for doing it at all. Let me give you just one illustration. We have on our grounds a movable pig-pen or pig-yard, made of galvanized iron wire. This pen is about 10 x 16 feet. When not in use for pigs, one of our boys uses it to confine sitting hens. A few days ago he raised up one side of it to let a sitting hen out that had been confined for a sufficient length of time. As he stood near the opening, she did not come out; therefore he called a stout man from his work, a little distance away, and asked him to hold up one side of the pen while he flopped his arms and "shooed" on the other side, to make biddy go out. Either from stubbornness or from lack of sense, however, biddy did not embrace the opportunity of regaining her liberty. At that time I came up.

"Why, H., why didn't you put a stick under the edge of the pen, and go about your other work and leave the hen to go out of her own accord, when she feels like it?"

Both men went back to their work, without making any reply whatever. Now, I meet almost constantly with people who are doing useless work—holding a heavy burden, as in the above instance, where nothing is accomplished at all, or, perhaps better expressed, where the same result might be attained without taking time or lifting heavy burdens at all. I sometimes think that, if people were working for themselves, they would use their wits more; but when I see people who are working for themselves, and working hard to make both ends meet, I will find them using strength and time, a great part of their time, where

a little thought would have saved both. Applying this same thing to bees, we lose by neglecting them at times; and, again, we disturb them when the same thing could be accomplished without disturbing them at all. Necessity is not only the mother of invention, but it is a good school where we are bright enough to be taught by it.

TRANSFERRING IN WINTER SUCCESSFULLY.

In GLEANINGS, Mar. 15, I find John Hobbs writes about transferring in winter. I have had some experience in this line this winter. A neighbor of mine gave me the bees from a box hive if I would give him the honey—or, rather, take the honey for him. I drove the bees into a soda-box and brought them home. I weighed them when I got home, and there were 2½ lbs. of bees. I turned them loose on 4 combs of sealed honey and one comb without any honey. This was done Dec. 11, 1888. Feb. 4, 1889, the queen was laying well. At this time they are breeding well. This colony is as strong in bees now as any I have. My bees have wintered well, and are building up well; are gathering some honey from peach-blossoms.

B. C. GRIFFITH.

Griffith, N. C., Mar. 25, 1889.

Why, friend G., as I understand it you transferred only the bees and not the combs of brood. This is a very simple matter, and can be done at any season of the year; and, in fact, so can combs and brood be transferred if one is careful to observe all the conditions.

REPORTED DEATH OF A YOUNG LADY, FROM A BEE-STING, A MISTAKE.

In Notes and Queries, Dec. 1, you publish a report from an American journal, *Old Homestead*, that would be apt to lead the readers of GLEANINGS to believe that a young lady named Ella Baker was stung to death by a bee. Now, you know I don't say that you believe such a thing could take place. I feel sure that you are of the same opinion as myself—that a single bee-sting could not possibly cause death to a human being. The report is just like a good many more (artificial section honey, for instance); when they have gone the rounds of several publications they don't lose much, but rather the reverse. In the above case the bee-sting had nothing whatever to do with the young lady's death. Being a close neighbor, just a question of a mile, and knowing the poor lady personally, also having to report on the case for several journals, I am somewhat of an authority. The doctor's certificate stated that death resulted from convulsions and syncope—nothing about a bee-sting, you see. Her sister died at about the same age, in exactly the same manner, a few years ago. She was not stung. Miss Ella Baker received a sting on the side of her nose on a Friday morning, early. She did all her household duties during the Friday and Saturday. I myself saw her on Saturday morning. There was just a little swelling, but hardly observable, and no pain was felt beyond the first prick. On Saturday evening, late (9:30), she lay down on a sofa, and while there was seized with convulsions, and died almost instantaneously. She had been stung twice before, but it had no more effect upon her than the last time. There was no swelling observable after death; the undertaker particularly noticed this, and informed me of the same. This young lady has frequently been present when I manipulated

their bees. I used to drive them for her father when they wanted the honey, as they kept them in what in England are called straw skeps. I think the above facts ought to be known, as reports of death from bee-stings are apt to discourage would-be bee-keepers. It has also the effect of frightening one's neighbors (non-bee-keepers). I know that, just when the above sad event happened, people fought shy of my apiary for some time.

W. B. WEBSTER.

Binfield, Berks, Eng., Feb., 1889.

Friend W., we are exceedingly obliged to you. The above incident brings out vividly two important points; the first is, how such things increase as they travel from mouth to mouth; and the saddest part is, that the newspapers are so ready to give credence, or perhaps care so little whether a story be true or false, providing it is sensational. The second point is, that, through the agency of GLEANINGS, with the circulation it now has, we may find somebody in almost every neighborhood to give us a correct statement in regard to such reports. I think, friend W., you are a little too strong in saying that no one was *ever* killed by the sting of a single bee. We have had quite a few reports indicating that this may at times happen. In your own country, if I am correct, a man died, not long ago, from suffocation caused by the swelling produced by the sting of a single bee.

WINTERED WELL; THE TEXAS STATE BEE-KEEPERS' ASSOCIATION.

Bees have wintered well in this section. No loss as yet. For the last two weeks we have had some pretty spring-like days, and the bees were out in full force, gathering pollen from the elms. The horsemint failed last year, but the bees gathered an unusual amount of honey from the cotton bloom. As little as is said about it, the cotton is one of our best honey-plants. The Texas State Bee-Keepers' Association will meet at Greenville, Hunt Co., Texas, at the apiary of W. R. Graham, May 1st, 1889. Bro. Root will meet a hearty reception if he will come.

J. N. HUNTER.

Celeste, Texas, Feb. 28, 1889.

A SIMPLE AND EFFECTIVE WAY TO BIND BEE-JOURNALS AND OTHER PERIODICALS.

I have a way of binding my bee-journals that may be new to some of the readers of GLEANINGS. It was suggested to me by Mr. J. Y. Detwiler, of Florida, when he was at the International Convention at Columbus last fall. Get common safety-pins that are about an inch and a half long in the clear, and run one of the pins through near each end of the journal, and as far from the back as the pin, when shut, will allow. The pins can be bought for five cents per card, that has a dozen on. I use an Emerson binder till the year is complete, and then take the journals from the binder and put in the safety-pins so as to have the binder to use for the current year.

A REMEDY, BUT NOT ONE FROM A BOTTLE.

Another piece of information, though not relating to bee-keeping, may be of interest to young bee-keepers, many of whom may be tormented in "body (face) and mind" by pimples on the face, as most young men are at times, when otherwise in good health. After shaving, take a cotton or linen cloth and dip it in water as hot as can possibly

be borne, and apply to the face, and hold it there while it feels real warm, repeating three or four times each time of shaving. Young ladies who are similarly afflicted can try the remedy without shaving, if they like, say two or three times a week. Friend Root, this is a good medicine, and it doesn't have to be taken from a bottle either, so you needn't say any thing against it.

Auburndale, O., Feb. 28, 1889.

A. B. MASON.

Friend M., please give our friend Detwiler a vote of thanks. He is one of these odd geniuses, and it is just like him to have thought of a safety-pin to take the place of a binder. I feel proud of your compliment, doctor; that is, to the effect that I am a little suspicious of any thing that comes out of a bottle.

A PECULIAR CASE OF COMB-BUILDING; STEALING HONEY FROM HIVES.

After extracting from both sides of a thick frame of honey it was still very heavy, and I found a middle row of cells. I suppose it must have been built all on one side, and then, in moving it, have been given space on the hollow side.

I am a good deal away from home, and some one robs my bees. After cutting out the honey they scatter the frames anywhere, so that I have only three stands left, and expect to find those served the same way. I had lots of good dogs, but they are soon poisoned. I wish I knew how to catch the villain.

I wonder whether any of your lady correspondents have used a knitting-machine. Do they do good work?

I had a catalogue from W. Hill & Co., 100 West Madison St., Chicago, in which they quoted 20 cents per dozen for Willimantic thread. I sent \$2.40 for 12 dozen, and received a parcel on which I paid \$1.40 express charges, and it contained a miscellaneous lot of thread, but not one spool of Willimantic, and all so rotten that it is useless. I have written twice, and they do not reply.

GEO. E. HALES.

Lytle, Tex., Feb. 6, 1889.

Very thick combs often have a middle section, as in the diagram, friend H.—As knitting-machines are rather out of our line, I would advise those who know about them to answer direct. We give the name of the firm you mention, that others may not lose money in the way you have done.

CROSS HYBRIDS.

I have enjoyed your humorous sketches from time to time, and especially the Dutchman's Mule. If your artist could have seen me last spring transferring hybrid bees by drumming them from their old box-hive home, he could have had a sketch equally humorous. I knew they were *very* cross, so I fixed my smoker, as I thought, put on a veil and gloves, tied my coat-sleeves tight around my wrists, and, inverting the hive, placed the new one

on top, and commenced drumming. I had done so many a time with good results, but these were hybrids, and instead of going up they came out mad as hornets, and alighted on me until I was almost coated with them, biting and stinging the woolen coat I had on. I reached for my smoker, but, alas, it had gone out in a short time, and now the bees were finding a way under my coat, and stinging me very much. I stomped, kicked, and brushed them, but to no avail. They were flying around me furiously. I ran off about fifty yards, and found matters getting worse. I opened my coat, threw it back to discard it and bees together, forgetting it was tied around my wrists. There I was, coat off and behind me, hanging to my arms. If I had been handcuffed it would not have been much worse; at the same time, bees were stinging me about the neck and body. I finally liberated myself by tearing my sleeves badly, leaving the coat with many angry bees on it. I have these bees yet, but they are difficult to manage, even with the most precaution.

GEO. W. GEASLEN.

Oakland Mills, Md., Feb. 11, 1889.

Friend G., I can not understand, from your account of the affair, that you first smoked the bees thoroughly before inverting the hive. If you did not do this, you certainly ought to expect to be stung. Instead of waiting for the smoker to go out, you should have smoked the bees until you got them to fill themselves with honey before you did any thing with them at all. It astonishes me to read accounts of people being stung, much the way you were, just because they omitted or neglected, or did not know how to use the smoker. It is next to sheer madness for anybody to stir up a colony of bees first and then hope to quiet them down with smoke afterward. Of course, some colonies of bees at certain times of the year will bear it.

WHEN TO RENEW OLD COMBS.

I see that your journal is still improving, and is of vital interest to every one handling bees. I wish you to give an article on when to clean out old hives and start them anew. I have some in which the brood-comb is so old and thick that bees do not seem to want to raise brood in it, and will work above. If I cut it all out in the spring, will they make honey this season any more than a new swarm?

H. ROBERTSEN.

Henderson, Tenn., Feb. 21, 1889.

Brood-comb can be used a great many times, without being renewed; and when it must be renewed I would take out only the heaviest and thickest, and that which has many imperfect cells. To cut out all of the old comb at once would be a great mistake. It would cripple your bees, and the probability is that a great part of the old comb would be much better for brood-rearing than the new.

A COLONY OF BEES WITHOUT A HIVE, AND ATTACHED TO A LIMB IN JANUARY.

Inclosed please find a newspaper article about a swarm of bees in January. How is that for Southern Illinois? Bees had a fly almost every week this winter.

M. H. KUEHNE.

Olmstead, Ill., Feb. 11, 1889.

A few days ago, as Silas Coram was walking up the river-bank on the opposite side of the river

from this place, he discovered a swarm of bees hanging on the limbs of a bush on the brink of the river, about ten or fifteen feet above the water. At first he was inclined to think his optics were deceiving him; but on investigating the matter he found a good-sized swarm of bees apparently well satisfied with their place of abode, and almost as lively as if it were summer, or the mild days of early autumn. When our young friend reached home he reported his strange find to his father. A day or two after, the father and son took a hive to the place, and succeeded in hiving the whole swarm. To their astonishment they found a great deal of comb and considerable honey. The fact that there was honey at the place, proved beyond a doubt that they had been there several months. — *Goconda Enterprise*, Ill., Jan. 31, 1889.

There is nothing very strange in the above. Bees cluster on the trees in California or in warm climates, and build combs sometimes, and stay several years. They also do it now and then all through the Northern States; and if they had plenty of old tough comb it would be nothing strange if they should winter over in such a locality. As our winter was very mild until the first of February, it is not surprising that they were alive and well. Possibly with plenty of stores every one would have come through had they not been disturbed.

DYSENTERY; NOT A SERIOUS CASE OF.

I wrote to you some time ago about dysentery, and now two other hives are a little daubed on the front. They seem to be healthy, and look well. Now, the thing is, I have been in the habit of going to see them very often, and arousing them. Would not that cause them to gorge themselves with honey, and cause them to come out and soil the outside of the hive? or is it possible that they have got the dysentery? The honey that they have was gathered from the Spanish needle. Is not that good to winter on?

WARREN WRIGHT.

Ludington, Mich., March 18, 1889.

As nearly as we can judge from your letter, we should say that you have been tinkering with your bees too much. The stores they had were not necessarily bad. If the hive is not soiled to any appreciable extent inside, you do not need to be alarmed. Bees in healthy condition will generally, in early spring, soil the outside of the hive to a slight extent.

THAT WINTERING PROBLEM, AGAIN; SUGAR STORES VERSUS BEES.

I am obliged to friend Heddon for his reply to my inquiry relative to the wintering of bees. He can winter a colony year in and year out as successfully as he can his buggy-horse, but thinks at too great a cost, and hopes that "I see the point." Yes, I even feel the point and own the steel. Briefly, Mr. Heddon, p. 90, objects to extracting honey which has a low value and slow sale, to feeding sugar which has a cash value. If his object were building up an apiary, would it not pay him even to extract closely and feed sugar? One dollar's worth of best sugar fed at the right time, bees carefully hid away, ought to winter them, when they surely ought to be worth five dollars in spring.

Beason, Ill.

J. HAMILTON.

You are right, friend H. It is very poor policy indeed to let bees starve to death, when, by investing in sugar to the extent of one-fourth their value, or less, they could be saved.

A FLOOD IN CALIFORNIA.

We have just had a flood, from March 16th to 17th; 10 inches of water fell at our house, making $22\frac{1}{2}$ inches to date. One mile further up the Sespe they got 13 inches. Some houses were washed away in Santa Paula. I suppose it was very disastrous in Los Angeles. The trains are stopped on account of washouts. The papers call the creek in front of our house the "Raging Sespe." The name was not appropriate when you were here; but if you could have seen it on the 16th, bounding and roaring like Niagara, you would not wonder at the Indians thinking there were "devils" in it. I am acting now on the supposition that we shall get a honey crop this season.

J. F. M'INTYRE.

Fillmore, Cal., March 18, 1889.

REPORTS ENCOURAGING.

NO LOSS IN WINTER.

LAST fall I had 42 good swarms. I packed part of them in fine oat straw and chaff, on their summer stands, and put part of them in my bee-cellar, which is in sandy soil, and properly ventilated. On the 18th inst. I took 5 swarms out of the cellar; on the 20th I took out 3, and on the 22d I took out the rest of them; and now on this 23d day of March I have just 42 good swarms, gathering pollen quite lively.

Coral, Mich.

L. W. ITZENHOUSER.

You ought to see the bees working on the red-mapple bloom, getting honey and pollen.

Lincoln, Tenn., Mar. 13, 1889.

T. P. GILLHAM.

ONLY ONE DEAD OUT OF SIXTY.

My bees, sixty swarms, have wintered well. Only one is dead out of sixty. I had to move them out of our village 2 years ago, away up on a side hill, since which I have not done so well.

J. E. TODD.

Unadilla, N. Y., March 15, 1889.

WINTERED WITHOUT LOSS.

Bees have wintered here well this time. I wintered 93 on summer stands, and have not lost any; lost only 4 queens. Bees have been very busy on soft maple and elm. Red-bud is just bursting.

Alma, Ill., Mar. 19, 1889.

RICHARD EDMONDS.

COLONIES NEVER WINTERED BETTER.

I am happy to say that our success in wintering my bees has never been better. We went into winter quarters with 48 colonies; and to-day, March 18, 45 are in good condition; 3 died of starvation, which was my own fault. The bees are busy bringing in natural pollen, and the prospects for the coming season were never better.

FRED LEININGER.

Douglas, Ohio, Mar. 18, 1889.

EARLY POLLEN; THE GOLDEN BEE-HIVE.

Bees are gathering pollen now to some extent; mine are all strong, or seem to be, from the way they are at work; but I have not examined any of my hives. I have only lifted the top and taken a peep in. I am the only one who has any Italians in this county, so far as I know. Some others use a frame hive; it's a patent trap, and known to the trade as the "Golden" bee-hive. I make my own hives, and they are modeled after the Simplicity. I have sold some of them to owners of the Golden bee-hive after they paid \$10.00 for a right for it.

Moltke, Tenn., March 22, 1889.

S. L. MEDLIN.

WINTERED WITHOUT A LOSS.

My bees have wintered well. I have not lost any. In examining them a few days ago I found brood in all the hives, and plenty of food to do them until they can gather new honey. They were taking in pollen quite lively on Sunday, March 24.

Clachan, Ont.

E. J. PURCELL.

WINTERING AT THE AXTELLS'.

We have taken 30 colonies of bees out of the cellar, because we had so many in the cellar we could not keep it cool enough. Those taken out have wintered finely—better than those out of doors. They were gathering pollen nicely yesterday, the 19th, which is earlier than usual by two weeks.

Roseville, Ill.

MRS. L. C. AXTELL.

WINTERED WELL; THE STRONG DRAWING FROM THE WEAK.

I took bees out of cellar yesterday, 68 hives, one dead; examined them all to-day. They are in the best condition, cleanest and strongest I ever had them. They gathered some pollen to-day. One trouble is, that a good many hives catch bees that do not belong to them, making themselves strong at the expense of others. You may remember, page 11, Jan. 1, 1889, that I wintered this time with the heavy cloth mat removed, and only a piece of burlap over the front half of the frames. It is a perfect success this time, certainly.

Grinnell, Ia., Mar. 20, 1889.

J. F. WHITMORE.

LOOKING FOR A "WHOPPER."

At this date my bees have wintered well. They seem to be stronger than they were last fall. I went into winter quarters with 29 stands; one starved; another was queenless, and I united it with another colony, so I have 27 stands yet. They have plenty of stores, and are breeding rapidly. We have had a very mild winter. I winter on the summer stands, packed with chaff. My bees commenced gathering pollen March 16th. The prospect for a "whopper" this coming season is very flattering. There is an immense crop of white clover, or will be, if the season is favorable. It is looking fine at present.

Paris, Ill., March 21, 1889.

J. P. ADAMS.

FROM ONE WHO OWNS NEARLY 600 COLONIES, AND WHO SHIPPED COMB HONEY BY THE TON AS EARLY AS 1857.

The bees seem to be wintering well so far here. Of course, it is too early in the season to make a safe prediction as to the honey crop of the coming summer. We only know that, so far, they have wintered well. But it is in the next two months that we meet with our greatest loss, especially when cold bleak winds prevail during this time. I speak somewhat from experience, this being the thirty-sixth year of my experience in bee-keeping. As early as 1857 I was shipping comb honey by the ton. This was considered a large amount of honey to be raised by one bee-keeper at that time; but now it is not uncommon to ship many times that amount. I went into winter quarters last November with over 550 colonies. They seem to be doing well. For this I feel encouraged, and hope that they will continue so to do.

We are naturally looking for and expect a good season this year, from the fact that last season was a very poor one, there being no basswood bloom in this section of country, and the yield of clover and other kinds was very light.

Exclusive of the extracted, my comb honey weighed but a little over five tons when it should have been many more. As many of the writers for the journals predict a great honey season this year I will join, and say I hope their prophecy may prove to be true. J. R. TUNNECLIFF.

Van Hornesville, N. Y.

NOTES AND QUERIES.

We solicit for this department short items and questions of a practical nature; but all QUESTIONS, if accompanied by other matter, must be put upon a SEPARATE slip of paper with name and address.

THE 10 lbs. of Japanese buckwheat seed I got from you last season gave me 15½ bushels, measured. I had 4 acres of the silverhull, and got only 25 bushels from it.

JOS. F. BILDERBACH.

Rockwood, Ill., March 29, 1889.

Please tell me where you put the tarred paper in the chaff hives.

MRS. A. A. SIMPSON.

Swarts, Pa., Feb. 6, 1889.

[The tarred paper on your chaff hives is put between the bottom-board and the chaff. See further particulars in our A B C of Bee Culture.]

How many bushels of chaff will it take to fill five chaff hives?

V. BUXSER.

Justus, Ohio, March 14, 1889.

[We usually calculate on about three bushels of loose chaff, not packed, to the two-story hive, and a little over one bushel for the one-story hive.]

WHITE PAINT FOR HIVES.

I prefer white paint to any other color, and I have tried several. Bro. Root, go on with your Home talk, and may God's blessings rest with you and yours.

S. C. FREDERICK.

Arcadia, Kan., Jan. 24, 1889.

[The general testimony is with you in regard to white paint for hives.]

MELISSA.

According to your description of melissa, it grows sometimes to the height of 9 feet. I planted a little last year, but it didn't attain the height of one foot in good garden soil. Perhaps mine was a small variety. The seed wasn't from you.

Chandler, Ind., Feb. 21, 1889.

A. HEINE.

IMPORTED CARNIOLANS SHOWING YELLOW BANDS.

We are expecting a fair honey crop this season, from present indications. Our Carniolans are booming; have had them three seasons, and find them equal to the best. But our imported queen from Benton shows many yellow workers.

Avon, Ind., March 18, 1889.

A. A. PARSONS.

SETTING OUT A SMALL APIARY.

I want to lay out an apiary for about 25 or 30 colonies, and set out grapevines. How near, and in what position ought I to set them? I am building a board fence on the north side of my lot. The bees will be on the south side.

J. BILLS.

Southington, Conn., Mar. 23, 1889.

[The conclusion to the A B C of Bee Culture gives you the plan which we prefer to arrange hives, and also their entrances with reference to the points of the compass. Six feet apart is the usual distance from center to center. Some prefer eight feet. The latter distance means just so much more traveling to get through with a certain amount of work.]

STIMULATING BROOD-REARING.

I wish to ask you if I may begin safely to stimulate brood-rearing by means of the "Good" candy.

Dayton, O., March 5, 1889.

T. B. REYNOLDS.

[You can stimulate brood-rearing with the Good candy; but an easier way would be to give them sugar syrup. Good candy is used, as a general thing, for the purpose of shipping bees, and for winter feeding, although it can be used for other purposes.]

NO LOSS IN CHAFF HIVES; DOUBLE-TIER WIDE FRAMES.

I keep 50 colonies of bees. I winter on your plan, and had no loss last winter nor this. I am getting tired of double-tier wide frames. Can you suggest a better arrangement for the chaff hive?

A. G. MENDENHALL.

Economy, Ind., Feb. 23, 1889.

[Use single-tier wide frames, or the T super or the section-holders described in GLEANINGS for Mar. 1st.]

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

All queries sent in for this department should be briefly stated, and free from any possible ambiguity. The question or questions should be written upon a separate slip of paper and marked, "For Our Question-Box."

QUESTION 118.—a. How large an entrance do you allow each colony when they begin to work in spring? b. When do you enlarge this, and how much?

a. Four inches wide; b. I do not enlarge.

R. WILKIN.

a. About 1½ inches wide by ¼ high. b. I enlarge as soon as the colonies get strong and weather warm.

GEO. GRIMM.

It varies with strength of colony, but it is small. Vary to suit size of colony. Make full size as colony gets strong and nights warm.

A. J. COOK.

a. 3x%. b. As soon as the season becomes so warm that they seem to need more ventilation, or as soon as they begin active honey-gathering.

JAMES A. GREEN.

I allow as large an entrance as the bees will use, whether for one bee to enter at a time, or the full width of the hive, and I'm not troubled with robbers.

A. B. MASON.

Three or four inches; we enlarge the space according to the number of workers flying out. We raise the hive 2 inches in front in the summer in very hot weather.

DADANT & SON.

No set size, but it depends on the strength of the colony; usually as small as can be without danger of clogging. We enlarge it according to increasing strength of colony, and sometimes it is one inch by ten.

P. H. ELWOOD.

When in spring I contract my brood-chambers in order to stimulate breeding up, I contract the entrances to about an inch, and remove the blocks after the colonies have become strong, and more air is desirable.

CHAS. F. MUTH.

a. Just as small an entrance as possible, without retarding the bees while passing in and out. b. I follow no special rule in this, as much depends on the size of colony, weather, capacity, and style of hive, kind of honey we are working for, etc.

O. O. POPPLETON.

In all strong colonies, the full size of the entrance. Contract the entrance to weak colonies only, and in proportion to their strength at all times.

H. R. BOARDMAN.

I use the same entrance all the year round— $\frac{3}{8}$ x 12, and in summer I have to raise the cap, for top ventilation, otherwise bees cluster too much outside.

P. L. VIALLO.

I vary it according to the strength of the colony, and enlarge it as the season advances. During the best of the season I prefer them to have abundant entrance. The whole width of the front of the hive is desirable for the best stocks. L. C. ROOT.

a. If the colony is weak, I put up both triangular blocks, leaving about two inches of space, and if the weather is cold and *windy* I do the same by the strong ones, to prevent the wind from chilling the young brood. b. As the season advances and the weather gets warm.

MRS. L. HARRISON.

a. Theoretically, just as small as they can use without being crowded, but frequently it happens to be much larger. An opening two inches by one-half is likely to be large enough for a strong colony. b. When the entrance appears crowded it is enlarged perhaps once to double size, and when this becomes crowded they are allowed full width.

C. C. MILLER.

I use an entrance from $\frac{3}{8}$ to $\frac{1}{2}$ inch high, and clear across one end of the brood-chamber. I contract with L. blocks, according to strength of colonies; strength, not in relation to heat, however, but to defense against robbers. As the tendency toward robbing decreases and the colony becomes strong, I give them the whole entrance.

JAMES HEDDON.

My hives have six $\frac{3}{8}$ holes at the bottom of hive, and a hole one and one-half inches half way up, with a $\frac{3}{8}$ -inch hole cut into the side of the large hole. In the winter we leave all six of the lower holes open and the small $\frac{3}{8}$ -inch hole up the side open. When the weather gets warm, and the bees strong, then we open the $1\frac{1}{2}$ -inch hole, which is covered with a button during the winter.

E. FRANCE.

a. $\frac{3}{8}$ x $\frac{3}{8}$ for the very weakest, and from there up to 3 inches by $\frac{3}{8}$ for the strongest. b. Along as they need it, which is told by their being crowded for room to go in and out at the entrance, or when they are crowded out in hot weather. In summer I give the whole length of entrance, which is 13 inches long by $\frac{3}{8}$ high. With very large colonies, and at times of extreme heat, I sometimes raise the front of the hive an inch or more from the bottom-board.

G. M. DOOLITTLE.

Sometimes I let a strong colony have the whole doorway of $\frac{3}{8}$ x 10 inches. Others are all the way down from this to a little hole scarcely large enough for two bees to pass each other. It is not absolute time, but the weather, and the growth of the colony, that determine when to give more entrance. A safe rule is to give the working bees room to pass without delaying, and beyond that widen the door only when you see some inclination on the part of the indoor bees to remain outside. Sometimes a colony gets weak in old bees just before a big batch of brood comes out, and needs a decided closing-up for a few days, if a cold spell comes. F. E. HASTY.

I watched the answers to the above, to see if there were not somebody who had come to the same conclusion we have, that,

unless the colony becomes weakened, the entrance should be full size the year round, especially for a protected hive like the chaff hive. We once practiced contracting entrances in winter; but by keeping a careful record we proved unmistakably that colonies with the entrance wide open $\frac{3}{8}$ x 8 wintered better than where we fussed to contract them when the weather was severe. Of late years we have not tried to winter a colony so weak that it could not have full entrance the year round, and I think losses from wintering, and robbing too, would be greatly lessened if something of the kind were adopted; namely, wintering none but strong colonies, and these with entrances full width the year round.

QUESTION 119.—*a. When bees are storing surplus, do you give any ventilation besides at the entrance? b. If so, where and how much?*

No.

P. H. ELWOOD.

No.

O. O. POPPLETON.

a. Yes; raise the covers.

MRS. L. HARRISON.

No. I do not wish any other. I believe it is a damage.

A. J. COOK.

No. A good shade-board besides the entrance is ventilation enough.

A. B. MASON.

No, unless I raise the hive in front, as spoken of in No. 118.

G. M. DOOLITTLE.

I do not. I have tried it, and found more disadvantages than advantages by so doing.

JAMES HEDDON.

As stated in question 118, I use the same entrance, but raise the cap about $\frac{1}{2}$ inch for top ventilation.

P. L. VIALLO.

In very hot weather I give ventilation around the surplus arrangement, but the bees can get out only at the entrance of the hive.

GEO. GRIMM.

In tiering up my hives I ventilate at the upper entrance, as well as the lower. I secure comb honey in wide frames, in full hives, mostly.

H. R. BOARDMAN.

a. Usually. b. At the top of the hive, back end—about $\frac{1}{4}$ inch the width of the hive. I think it helps to keep down swarming, but it hinders work in the back end of super.

C. C. MILLER.

We give no ventilation except our regular entrance. We have a $1\frac{1}{2}$ -inch hole half way up the side, open in the summer, and the bees usually fly right into the hole; sometimes they catch on the side of the hive, and then run in.

E. FRANCE.

I consider no hive satisfactory without a good-sized ventilator in the bottom-board. In the warmest weather a ventilator 6 x 12 inches may be left entirely drawn. I also consider upward ventilation advantageous at times.

L. C. ROOT.

Not as a rule. If a colony seems to be suffering from the heat I raise the cover a little, the amount of ventilation given being according to circumstances. Usually, though, when I give any I give an abundance, often removing the whole cover.

JAMES A. GREEN.

When more air is necessary or desirable than bottom ventilation gives, I break loose the covers of the surplus boxes, scrape the bee-glue off, and put

them on again. Then I raise the cover about an inch, on the back part of the hive, creating thereby an air-passage over the surplus boxes.

C. F. MUTH.

a. I do. b. When the weather becomes so hot as to make bees lie out, or to endanger the melting of combs, I fold the duck-cloth cover forward 2 or 3 inches, off the frames, and leave the rear end of the board cover, that lies on it, elevated an inch or more by placing a stone under it. R. WILKIN.

When we think that our 8-inch entrance is not sufficient, i. e., when the weather is warm and the crop begun, we place a block to raise the hive from its bottom in front. Besides, as our colonies are very populous we push back the surplus box, so as to get a current of air through the hive.

DADANT & SON.

Many of my hives have no provision for ventilation of the super; but my accepted way of making a hive is to have a crack a quarter of an inch wide or more run clear around the hive between the lower story and the super. To prevent the obvious ill consequences of this arrangement the whole top is covered with what I call a shirt, so the wind must first filter through muslin before it can blow in. Does the improvement increase the surplus? Well, it's pretty clear that extra ventilation has a chance to be of direct profit only when honey comes in so rapidly that the bees find difficulty in evaporating it fast enough. I am not quite settled in mind as to how often this happens—rather seldom in my locality, I judge. E. E. HASTY.

At one time I made many experiments in regard to entrances; and once I was very strongly decided in favor of a two-inch auger-hole in the front end of the hive. The bees then could fly right in and alight directly on the combs; and I would stick to the auger-holes now were it not that it hinders brood-rearing for some distance around the hole when the weather is severe. Other experiments in this line made me feel sure that the entrance should be at the bottom of the hive. And then I was very strong for a time in favor of having a large entrance right through the middle of the bottom-board, and I would still stick to this plan were it not for the difficulty of closing the entrance when we wish. All things considered, I made a compromise by pushing the Simplicity hive so as to project over the bottom-board. This enables you to adjust the entrance to the size of your colony, and you can do it in an instant, without any blocks or loose traps lying around. When you come to ventilate, you can make the bees go in the hive by giving them an entrance nearly half the size of the whole bottom of the hive if you wish. When hiving new swarms in hot weather I think this is very much to be desired. The objection to openings for ventilation, covered by wire cloth, is that they invariably get waxed up sooner or later.

QUESTION 120.—a. *What kind of an alighting-board do you prefer during the rush of incoming laden bees?* b. *Does it pay to have a bare spot of ground near the entrance, covered with sawdust or sand nicely patted down?*

a. A board 10 or 12 inches wide. b. I guess not.

MRS. L. HARRISON.

I prefer a board from the ground to a level with the alighting-board. C. F. MUTH.

Any kind of board will do. Sawdust and sand are not as good, and too much trouble. GEO. GRIMM.

Simply have the ground kept clean and clear about the entrance. It does pay.

H. R. BOARDMAN.

a. A slanting alighting-board is best. I think short grass is cooler than bare ground or sawdust.

P. H. ELWOOD.

a. A plain board projecting three or four inches. Others may be as good. b. Probably, if easily obtained.

C. C. MILLER.

a. Inclined wooden. b. I used to have it. I have exchanged to smooth closely mown lawn. This latter looks better, and is practically about as good.

A. J. COOK.

My entrances are all within 2 inches of the ground. I keep it clean in front of the hives. In the honey season the dry sandy soil can be graded up to the entrance.

R. WILKIN.

The alighting-board should be about one foot wide, and as long as the width of the front of the hive. This is sufficient if the grass and weeds are kept down.

L. C. ROOT.

a. Our bottom-board is at least six or eight inches, or more, longer than the hive. b. We take care to cut the weeds away in front of the hives, and, of course, all around. Sand is *very* good with a sloping apron.

DADANT & SON.

Besides the detachable alighting-board I use a slanting board from the ground to the alighting-board or entrance. I find sawdust dangerous around hives, as sparks from the smoker are liable to set it on fire.

PAUL L. VIALLO.

The only alighting-board my bees have is the projection of the bottom of the hive, $3\frac{1}{2}$ inches, and the front is close to the ground. b. Perhaps it does, but I like a closely cut lawn the best, after having tried bare ground and sawdust.

A. B. MASON.

a. Simply an extension of the bottom-board, the same extending six inches in front of the hive. b. I lay a cleated board down in front to keep the grass down, then when the lawn-mower is run in front of the hive this board is taken out of the way, so that all is smooth work.

G. M. DOOLITTLE.

I strongly prefer a level or slightly slanting board of generous size, with arrangements so that bees which fall to the ground can readily crawl up in. b. I am willing to take considerable pains to secure a clean dooryard for them. As to sawdust, I find myself getting a little out of conceit with it.

E. E. HASTY.

I prefer to have the bottom-board enough longer than the hive to form an alighting-board. I think it pays to have not only the ground near the entrance, but all around the hive, bare. My apiary is covered with slack coal, ashes, sand, etc., so thickly that grass or weeds seldom struggle through.

JAMES A. GREEN.

a. Any kind of wide board, so arranged as to avoid having sharp corners or crevices to obstruct the direct passage of bees into the hive. b. I prefer a spot of bare ground to either sand or sawdust, if there is some practicable way to keep it bare. Who can tell us how to do that cheaply and easily?

O. O. POPPLETON.

We don't use any kind of alighting-board; our bees are nearly all located on pasture ground. The stock keep the grass short about the hives. I don't think I should like sand or dry dust at the entrance of hives.

E. FRANCE.

I find it makes but little difference. I believe that bees soon learn to use the most convenient and natural places to alight, but I do not believe that the laden bee prefers any other alighting-place to a vertical surface. Watch them in a box hive with a front hole part way up the front side. See what a large proportion will alight on the side of the hive. It makes no difference whether that hole is at the top or bottom. As they come to the hive laden, with their abdomen hanging down, they delight to alight upon an upright surface. They are built just right for it, you know. Yes, sir, I always keep a bare spot on the ground in front of the entrance. I use sawdust in conjunction with the hoe.

JAMES HEDDON.

Now, in view of my answer to 119 I should say the best alighting-board in the world is a clean piece of ground, right round the entrance, covered with sand or sawdust. As the sawdust is liable to catch fire from the smoker, we have of late years adopted white sand. But this white sand would not answer at all unless you keep weeds from growing in it; therefore you want to make your sand white with common salt, about once a year, and then you have it. By no manner of means can we afford to have our bees knocked down and wearing their wings into ragged strings by buzzing them against grass and weeds when they are trying to get into their hive. Some have argued that the bees will get just as much honey, even if they do have to crawl through the grass and weeds. Please remember, friends, that a bee gathers honey until his wings are worn out; and I shouldn't wonder if the life of a worker were shortened almost half by buzzing against the grass and weeds I have seen in some apiaries, while trying to get into the hive. I do not like a board, because it warps under the influence of the sun and rain. True, it can be cleated; but even then the sun will pull the nails out, and toads and spiders, and may be snakes, will get under the board. The sand and salt make a clean job of it. Some experiments have been made with cement; and in California, where they do not have any frost, I think it would answer admirably. A nice flat stone, with the bottom-board of the hive lapping on the stone, so no grass or weeds could get between the stone and the bottom-board, would do splendidly. I am not sure but that we could get pieces of sawed flaging, one foot wide and fifteen inches long, cheap enough so they would be worth all they cost. You would have an entrance and dooryard then that would last a lifetime. The cold stone might give the bees the toothache on frosty mornings, unless it be true that they never fly when the stone would be cold enough to be disagreeable. Friend Heddon's reasoning is good; but I do not like that hole in the front end of the hive, because it chills the brood-nest; and when the same hive is used for an upper story, you have an entrance where you do not want it.

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from \$1.00 to \$1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows: viz.: Sheer Off, Silver Keys, The Giant-Killer; or, The Roby Family, Rescued from Egypt, Pilgrim's Progress, and Ten Nights in a Bar-Room. We have also Our Homes, Part I., and Our Homes, Part II. Besides the above books, you may have a photograph of our old house apiary, and a photograph of our own apiary, both taken a great many years ago. In the former is a picture of Novice, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

BEES IN THE CELLAR DID THE BEST.

Last fall my pa packed 59 swarms of bees for winter. He had 38 in the cellar and 21 outdoors. He lost 2 of those that he left out. Pa says it seems as if those he put in the cellar almost doubled. I have a little brother. He will be 3 years old the 10th of April. He is a dreadful little mischief. Sometimes I help pa extract honey. The name of his extractor is "Novice," and he says that means you. In the spring of 1886 he bought 20 colonies of bees of Mr. Hunt, of Bell Branch, Mich., and we commenced to take GLEANINGS again, and I guess we always shall. I like the little letters and your travels. Ma likes Our Homes, and pa likes it all. That kite I got of you is almost as good as new.

Starville, Mich.

MABEL M. COOK, age 9.

THAT BABY SISTER.

Yesterday, Feb. 22, the bees had a good cleansing flight. Papa says they have consumed more honey this winter than ever he knew them to do before, and it has been a mild winter too. Upon examining them yesterday he found a great many colonies short of stores, and two had starved. Mr. Root, the notes that you have given us in GLEANINGS of your trip to California have been very interesting. Mamma reads Our Homes to us Sunday evenings. I like to see the pictures of the beekeepers. Why not give the picture of your little boy Huber? I should like to see him, and pinch his little fat cheeks. I can remember him as I saw him a little baby. He had just learned to walk. I have a little sister, 26 months old to-day, and she weighs 42 lbs. She is just as dear a darling as can be.

GERTRUDE SEABRIGHT, age 9.

Blaine, Belmont Co., O, Feb. 23, 1889.

HOW BEES PROTECT FRUIT, AS TOLD BY A LITTLE GIRL.

My uncle has 30 swarms of bees, wintered in chaff hives, doing well. He has mulberry-trees in the yard with them, and they have berries on, and the wild canary likes the berries as well as I. Uncle has one tree among the bees, and the birds did not touch them. It was full of berries, and from the others we had to shoo the birds off. Auntie says she is going to have uncle put a hive under every tree, and that will be seven, and see if the bees will

keep them away as it has from that one. I go to school. Auntie has a little dog. His name is Fido. His wool is as white and long as that of Mary's lamb; and everywhere I go he is sure to go. I tell him the bees will sting him if he doesn't look out.

OLLIE AYERS, age 8.

Wallaceburg, Ont., Mar. 23, 1889.

Very good, friend Ollie. I think Prof. Cook can tell us something about bees frightening the birds away, and this suggestion of yours *may* prove to be of *great* value.

"OUT OF THE FRYING-PAN INTO THE FIRE."

My papa has between 50 and 75 swarms of bees. He and I hive the bees in the summer when they swarm. Last summer papa said he would give me 25 cents for every swarm I would hive without help. I got between 3 and 4 dollars. I had a veil that I put on sometimes when the bees were cross. My papa's bees are Italians and Carniolans. He gave me a swarm last summer, but it died. I like bees very well when they do not sting me. Once I got a sting on the elbow when I was up in the top of a large cherry-tree shaking some bees off from a limb of the tree. I jumped, and landed in a bunch of briar bushes.

CHARLES H. MASON, age 12.

Mechanic Falls, Me.

Why, friend Charlie, we don't believe you bettered yourself by jumping, especially since you landed among the briars. A bee-keeper must learn to "grin and bear it."

KEEPING THE BEES IN WITH SNOW.

Papa moved our house down on the road last September, and our barn too. He did not get his bees down here till the 27th of February. There was some snow on the ground. Papa put some snow in front of the hives where the bees came out. It had begun to thaw, and the bees came out of the hives after he brought them down here. Papa has 18 stands of bees. He has had but one stand of bees die this winter so far, but it did not freeze to death. It did not have enough honey. Papa had good success last summer.

BERT PRESNALL, age 13.

Marion, Ind., March 1, 1889.

But you don't tell us whether any of the bees that got out went back. We should presume that some of them, at least, must have gone back to where they used to live, and died there, because they hadn't any hive to go into.

BEES WORKING ON RED ELM; MAKING THE RIGHT KIND OF A START.

I hope you will forgive a little boy for slipping a note into papa's letter while he is out making a hot-bed. I want to tell you about our bees. I was out walking with brother Ernest (named after Mr. Ernest Root) and mamma, when I heard such a roaring and humming I stopped to listen and ask mamma what it was. She told me to look at a large red-elm tree just in front of us. It was in bloom, and I think every bee out of papa's 30 stands was on or around the tree. They were so high I could not tell what they were gathering. My little brother and I are going to try to be good men when we are grown. We both say our prayers every night, and try to mind what we are told.

WILLIE E. BARNES.

Hickman, Ky., March 14, 1889.

Bees do work on the elm, and it is quite a sight to see them too. We are glad you and

your brother have *started* right. We hope you will keep right on just so all your lives. If more of the boys in the land were making such a *good* beginning we shouldn't have so many bad men, should we, Willie?

PAPA'S FRAME-HOLDER.

My papa, finding the necessity of some kind of receptacle for holding the brood-frames after removing them out of the hives in the fall, in preparing them for packing for winter, has invented what he calls a *frame-reel*, of which I send you a drawing. He has it in one corner of our honey-house. It does not take up much room. It consists of four upright posts and 16 side-bars for the frames to rest on. The reel revolves on two pivots, one on the floor and the other in the ceiling. Each tier holds 18 Simplicity brood-frames, or 144 in all.

CHAS. SEABRIGHT.

Blaine, O., Feb. 25, 1889.

Your papa's device is very ingenious, and we are sure it will do nicely. It should be made strong, so as to hold combs filled with honey. After all, we should rather prefer to store the combs away in Simplicity hives, stacked up. Then if robbers *should* get into the honey-room they can't get at the combs. Hive-bodies are convenient; and whenever there is a surplus of combs there is a surplus of bodies.

JUVENILE POETRY.

Oh! here comes the honey-bee,
With rich and prudent air;
He has worked hard all summer,
Among the flowers fair,
And filled his hive with honey
From bottom to the top.
So that, when winter comes,
Then he starveth not.
But the winter is coming,
And he must be stored
In the nice warm cellar,
Away from the cold.
But he has prepared for it
All through the summer long,
And did not sit idle
As the lazy drone,
But went to work in earnest
Among the flowers fair,
That bloomed so freshly
With fragrance rich and rare,
So that when winter comes
With its wind and snow,
That he should be prepared
In the warm cellar to go.
The bee is very useful
In odd and different ways,
So then we should be thankful
While he with us stays. KATIE M.

The poetry above is not *entirely* faultless as to measure and meter; but as it bears the stamp of originality of a little girl, we gladly give it a place.

TOBACCO COLUMN.

CONDITIONS UNDER WHICH WE GIVE SMOKERS TO PERSONS WHO STOP USING TOBACCO.

First, the candidate must be one of those who have given up tobacco in consequence of what he has seen and read in this department. Second, he promises to pay for the smoker should he ever resume the use of tobacco in any form, after receiving the smoker. Third, he must be a subscriber to GLEANINGS. Any subscriber may, however, have smokers sent to neighbors or personal acquaintances whom he has labored with on the matter of tobacco-using, providing he give us his pledge that, if the one who receives the smoker ever uses tobacco again, he (the subscriber) will pay for the smoker. The one who receives the smoker in this case need not be a subscriber to GLEANINGS, though we greatly prefer that he be one, because we think he would be strengthened by reading the testimonials from time to time in regard to this matter. The full name and address of every one who makes the promise must be furnished for publication.

TOBACCO, AND ITS CLOSE CONNECTION WITH WHISKY; A LETTER FROM ANNA B. QUILLIN.

MR. ROOT:—Ever since I became acquainted with GLEANINGS I have watched with a great deal of interest your determined but somewhat novel warfare against the use of tobacco. It has always seemed strange to me that so many people would indulge in the use of it, when it is not only useless, but expensive and injurious also. Many of those who are habitual chewers make themselves positively repulsive by their carelessness and utter disregard for cleanliness, while many who smoke make themselves equally disagreeable and offensive by puffing their smoke into the faces of those who not only dislike it, but are sickened by the odor. And did you ever notice how tobacco and whisky go hand in hand, as it were? Wherever intoxicating liquors are sold, there you will always find cigars. When you see men coming out of saloons, you generally see them puffing at a pipe or cigar; and though a great many good people indulge in tobacco and do not use intoxicants, yet those who are regular drinkers are almost invariably slaves to tobacco. The old adage, "An ounce of prevention is worth a pound of cure," might well be applied to this subject, for it would certainly be much easier to avoid learning the use of tobacco than to break off from the habit after it has been acquired, for it is acquired. I have heard many men give their experience on that point, and they invariably agreed that they "had to learn to like tobacco." But when the habit is once formed, people generally become slaves to it; and if the chains are ever broken, it is not until they have had many a sharp and severe struggle for their freedom. And the same may be said of those who indulge in intoxicants. I think the great hope for the future is to teach the young people and children the injurious effects of tobacco and intoxicants on the system, and thus help them to avoid forming evil habits that are proving a curse to humanity.

There is a little rhyme which may be new to some of the readers of GLEANINGS; and though it is not very elegant poetry, it contains a great deal of truth. If I am not mistaken, it was composed by a Methodist minister; but at any rate the gentleman had an intense dislike for tobacco, as the following lines will demonstrate:

Tobacco is a filthy weed,
And from the Devil did proceed.
It spoils your breath and soils your clothes,
And makes a chimney of your nose.

I know one district-school teacher who took pains to teach those lines to every boy who went to school to her, and I believe such teaching would not be without some good results. When our bodies are

the houses we live in, should we not try to keep them pure and clean, instead of polluting and destroying them? "Know ye not that ye are the temple of God?" "Know ye not that your body is the temple of the Holy Ghost?" ANNA B. QUILLIN.

Ipava, Ill., Mar. 12, 1889.

TOBACCO FORBIDDEN TO BOYS.

The 12th of the month is a little late to be reading the last GLEANINGS, but I was reading Mrs. J. B. Ratcliffe's letter, and I wanted to add my mite on the subject. I say, abolish strong drink first, and tobacco very soon after. We have a law in our State, forbidding the sale or gift of tobacco to boys under 16 years of age, under a penalty of \$20 for each offense; but it is poorly followed, I fear. I represented our town in the last meeting of supervisors, when there was a bill of \$3.50 for tobacco for the use of the occupants of the poorhouse. The next morning I offered a resolution forbidding it to be furnished at the expense of the county. It carried by a two-thirds vote, men voting for it who were chewing and smoking when they voted. I think it is one of the causes of pauperism, therefore we should not supply it to the poor. You can enroll my name as one in the army to fight King Alcohol and Prince Tobacco. We expect at this session of the Legislature to get the privilege of county option, and then we will free our county of the curse of strong drink.

Our bees were foraging for maple sap or any thing in their line, this March 12th.

Philo, Ill.

M. L. BREWER.

AN INJURY TO HEALTH, AND A DISGUSTING HABIT.

A brother-in-law who had chewed tobacco for many years was obliged to leave it off because he came out with several cancers. He found, when he tried in earnest, he could leave it off; since then his health has greatly improved; but the cancers, as soon as cured in one place, come out in another.

Another acquaintance of mine, when cutting open a plug of tobacco, cut open a big tobacco-worm that had been mashed in with the tobacco.

A few days since I called at a store, and the proprietor had long whiskers, down which was drizzling tobacco-juice over at least one-third of his entire lower whiskers. What a sight!

Roseville, Ill.

MRS. L. C. AXTELL.

A USER OF TOBACCO FOR 30 YEARS QUIT.

I am glad to say, after over one month's experience, that, by the help of Christ, I have quit the use of tobacco in every way after I had used it for over thirty years. I can not say that I was influenced solely by GLEANINGS, but by seeing that others were quitting. I made a strong resolution, God helping me I would not only try, but I *would* quit. And I am surprised how easy it has been. I believe that *anybody* can quit who will lay it away and ask God for his grace to aid and strengthen. I will say here, that I am well convinced that, if I had never used tobacco in any form, I should have been a better man mentally, physically, and financially; and I advise everybody to quit the bad, filthy, expensive habit. Now, Mr. Root, if you think I am worthy of a smoker, if you will send me one I will pledge myself that, if ever I use tobacco in any form I will pay you the price of the smoker. I am a constant reader of GLEANINGS. We have been very much interested in your report of your travels.

T. N. STOKES.

Darlington, Ind., Feb. 6, 1889.

MYSELF AND MY NEIGHBORS.

For as I passed by, and beheld your devotions, I found an altar with this inscription, TO THE UNKNOWN GOD. Whom therefore ye ignorantly worship, him declare I unto you.—ACTS 17:23.

THE GARDEN OF THE GODS.

IT seems to me that the peculiar surroundings at Manitou strongly tempt one to think that he is in many respects in an enchanted land. The strange, grotesque rocks which I have already described, the springs that bubble forth delicious, sparkling, pungent, effervescing beverages; the sight of winter all around and a little above you, while you stand in a valley of perpetual summer, rather encourages the idea. When I started off on my walk that morning I was watching anxiously every foot of the way, to see glimpses indicating my approach to the Garden of the Gods. I do not quite like the name, for it sounds to me a little irreverent; but I can readily imagine that the discoverers of this strange

Arizona, of the work of the winds and water in wearing away rock. Some convulsion of nature during former ages had tipped the stratified rock up edgewise; then the whole had been covered with a debris of sand or soil, until the rocks standing edgewise were submerged. Now, if it were possible that some spring or other agency should cause a deposit of iron on the surface of this raised soil, so as to form a capstone of a yellow stratum, which became hard, and, after all this had taken place, the winds and floods should then wash away the soil so as to leave these rocks, that were originally turned edgewise, standing up above the soil, with the iron-ore deposit resting on their points, I can readily imagine how Monumental Park and the Garden of the Gods, should be produced by Nature's workings.

The road is well traveled along here, for excursions from Manitou go out to the Garden of the Gods almost hourly, and therefore my road was an easy and pleasant one, although it was a good deal up hill and down. In turning abruptly through the evergreen-trees, which lined the road almost

"THE HAPPY FAMILY," MONUMENTAL PARK.

locality felt as though they must have some name for the strange objects that began to meet my view. One of the first things that attracted my attention was some queer rocks sticking out of the ground, looking more or less like monuments of some rude sort, or tombstones of some former age. Pretty soon, on the summit of a little knoll among the bushes, I caught a glimpse of some of these queer monuments actually capped. See cut above.

As I came around a curve in the road, so as to get a better view, I could hardly believe my eyes when I saw three of these pedestals united by a cap that formed a bridge from one to the other, as seen above. The three seemed to be supporting on their apex this piece of rock as if it were a log, or may be a human body, suspended aloft. I noticed at once that this log, and, in fact, all of the cappings, were of a different-colored stone, indicating that they were harder; and then I remembered my studies in

its whole length, I came suddenly upon what is called the Balanced Rock, as seen on next page.

As one lifts his eyes and gazes upon this ponderous stone, as big as a small meeting-house, he involuntarily starts back for fear it will tip over on him; and it took me quite a little time to gain assurance enough to walk boldly up and take hold of the rock to see if I could not tip it out of its place. Perhaps I should remind our readers that these pictures are true to life, for they were all made from photographs, by the new Ives process. As one sees the fleecy clouds float along the sky above the tree-tops, and above this rock, he is almost sure to imagine that the rock is swaying one way and the other, ready to roll on him and crush him to atoms. In fact, those who are familiar with the objects here have a sly trick of telling people, especially ladies, that this great rock sways to and fro, as the wind blows light or strong. After they have made many exclamations

of surprise, somebody begins to smile, and then there is a big laugh all round, to think how easily they have been humbugged. I hardly need tell our readers that all the lifting I could do did not disturb the great stone from its poise where it has rested for so many ages. The stones and rocks in this vicinity are much like those in the region of Mammoth Cave. They are more or less soluble in water; and as the rain trickles down it dissolves enough of them to give the water a plain color, so a great many of the streams are red, or yellow, on account of the chemicals they have dissolved from the rocks. This red, or yellow color, I believe, is mostly owing to the salts of iron. The Indian name for yellow is "ute," therefore we have Ute Canyon, Ute Mountain, and Ute Springs. The Ute Springs have enough

springs and ship it by the carload to distant places, where there is demand for it. Before we go on, let us look back and say good-by to our friend the Balanced Rock. The monuments and pillars of the Garden of the Gods are scattered over perhaps a mile or two of ground. Some visitors have been disappointed because nature did not arrange them all in a group so they could be seen without traveling. I confess, however, that I rather like the idea of having them burst upon my view as I climbed hills and descended into valleys, one at a time.

The next thing was the Needle Rocks and the adjacent spires, the names of which I have forgotten—see next page.

The three rocks called the Needles are seen on the left. They are thin flat stones that stand straight up, perhaps a hundred feet or more high. Some think there is nothing to suggest needles. In fact, you might think them one, instead of three rocks; but when you get along to just the right point, as you look at them edgewise toward the sky you will see that they are entirely separated, clear to the ground, and all you notice is three thin spires, so frail you are tempted to think they must be sheet iron or they would be broken off by the wind. These three once composed a solid rock, sticking up straight toward the sky. As this rock, however, was composed of strata of different degrees of hardness, the wind and rain have dissolved out the soft portions, leaving the needles, or leaves, rather. Right back of the horse and buggy you will notice another strange pile of rocks, one of them reaching like a single tall spire away up into the sky, almost. You can get an idea of its height from the size of the horse and buggy. At the left of this square block, not unlike the ruins of some building, is another of these queer bridges. In this case, one of the spires has evidently broken off and fallen on its neighbor. The rocks a little further on, at the right hand of the picture, are full of openings not unlike the needles. In our next picture we have a view of them from the other side. The horse and buggy again give you something of an idea of their height.

And now we stand right in the center of the sacred ground. I say "sacred," because it seems to me that almost any child of humanity must feel like uncovering his head as he looks in awe and wonder at these strange and curious structures towering up like mountains. The picture gives you a faint glimpse of the roadways that have been made here and there in the sand. As you push your foot into the reddish-yellow soil, or, rather, gravel, you are impressed with the idea that these rocks, at some remote time, must have been very much higher than they are now, and that the ruin of their former greatness is what makes this rocky gravel that covers the whole landscape all round about. A little distance away is a hotel that is kept up in summer time. At the time of my visit they did not receive visitors. The lady who had the place in charge kindly answered my questions, however, pointed out the places of interest, and supplied me with the photo-

THE BALANCED ROCK, IN THE GARDEN OF THE GODS.

iron in them to give a slightly sour taste, not unlike weak lemonade; and the presence of the carbonic acid, to make the water sparkle, and give it the delicious snap, makes one almost ready to acknowledge, as the Indians used to have it, that the Great Spirit had given mankind not only a delicious beverage, bubbling up from the bowels of the earth, but a beverage that heals diseases while it refreshes. Now, Dr. Mason intimates, somewhere in this issue, that I am rather averse to any sort of healings that come out of a bottle. I want to tell him that I begin to have faith just at present in the virtues of Manitou spring water, even though we do have to bottle it up at the

graphs I have given you on these pages. Most of the rocks have been named; and people imagine that these rocks bear likenesses to different animals. As the rocks and cliffs are all variegated with different colors, mostly red and yellow, various landscapes and pictures are pointed out. These,

er, horses, passengers on top and inside, and luggage behind."

I smiled somewhat as I turned back, and now for the first time allowed my imagination to see in the coloring of the rocks what she had described. I have from childhood had a very vivid imagination, and can re-

NEEDLE ROCKS, GARDEN OF THE GODS.

however, draw so strongly on the imagination that few people can see them until they are "educated up to it," if I may use the term; and various maps and paintings adorn the reception-room of this hotel, giving an exaggerated view of the paintings to be seen on the rocks. For instance: Said the lady,—

member as long as forty years ago of seeing pictures in the clouds, and, in my mind's eye, building up a romance that so absorbed me it was like a fairy-tale or a story from the Arabian Nights; and when I found here at the Garden of the Gods that they were making a science, almost, of this matter of seeing wonderful paintings where the ordi-

VIEW OF THE INTERIOR OF THE GARDEN OF THE GODS.

"Can you see that stage-coach just on the summit of yonder range of cliffs?"

I was obliged to confess that I could not see any stage-coach at all—nothing like it.

"Well, now, turn around and look at the picture up there on the wall. You see there the old-fashioned stage-coach with its driv-

nary individual saw nothing at all, it made me smile again. For the first time since my long walk in the morning I began to feel that it was dinner-time; but my good friend told me there was no remedy. They were not prepared to give anybody a dinner, so I had the prospect of two miles and a half be-

fore dinner. I asked my friend if I could not shorten the distance by going crosslots. She said she believed the traveled road was considered the quickest and easiest in the end. I, however, though tired and hungry, rather preferred a new path. My wife has scolded me over and over again because I *always* insist on going home by some other route; and even though former experience has resulted in my getting lost, finding bridges gone, getting the buggy muddy, and things of that sort, she says experience *with me* does not seem to amount to any thing. I am up to the same old trick whenever I get five miles or more from home. I saw an opening through the rocky cliffs, right ahead of that horse and buggy, and into it I pushed, with my photographs in my hand. Pretty soon I had more climbing over the rocks than I had counted on; but I consoled myself by thinking it must be pretty soon down hill instead of up. Yes, it was down hill, but such a down hill as I never saw before. I pushed ahead until I began to fear I should fall into a chasm or be killed on the points of the jagged rocks below me; and then my imagination began picturing GLEANINGS dressed in crape, and all its readers saddened by the intelligence that its editor had been found crushed to death at the bottom of a precipice. So I got back to the beaten road, and, as soon as I could, made for the railway track.

What a boon is a railway track, even to a footsore and weary traveler! I had been saying to myself, that, if I just got on the railway track there would be no more up hill and down hill. But I soon had experience of this queer optical illusion that I have mentioned before, as the effect of the mountains; namely, you are sure you are going *down hill* when in reality you are on the up grade. I looked ahead on the track, and rejoiced at the prospect of seeing a place where it was so much down hill that I could easily run clear down to the town; but when I got there I could hardly believe my senses. It seemed to me as if some evil sprite from the Garden of the Gods were pulling and tugging at my coat-tails, and trying to pull me up hill backward. It seemed so unreal, that I turned square round and walked the other way. Would you believe it?—it was a great deal easier walking up hill (at least my senses said it was up hill) than to go down hill toward the town! I looked around for a stream of water. Sure enough! I felt like the woman who said, "There, it is just as I expected, and I *always* thought it would be." That contrary stream of water was running up hill, just as plain as the nose on your face. It seemed to be laughing and giggling to think I was such a "greeny." By and by, however, I reached my hotel; and my good friend who presides at the table had saved out an extra nice dinner for me. It was then only just half-past twelve o'clock.

Does some one wonder what all this story has to do with the text at the head of our talk to-day? Well, friends, it is this: Great multitudes are thronging Manitou, especially during the hot weather of summer. If they come here they put up at expensive

hotels, and then pay great prices for liversies to visit these things I have told you about. They do this to worship God through his works, some of them say. Now, they come here for enjoyment and recreation, and in order to get the very greatest amount of enjoyment out of a certain sum of money or for a certain number of days or weeks, and they resort to various artifices to enhance the attraction the place already possesses. Expensive hotels furnish costly viands; and the advertisements of their wonderful springs unblushingly recommend Manitou spring-water, combined with intoxicating liquors; and a good many people when they go out to enjoy nature must have a bottle of intoxicants along with them. I have sometimes wondered *why* one who loved whisky could not get intoxicated just as well somewhere out of sight as to go to a picnic or excursion, or on a trip to some noted watering-place. Many must have a cigar when they are looking at the mountains, waterfalls, or nature's caverns. Stumps of cigars are scattered quite freely all through the Garden of the Gods. I am told, also, that the livery-stables do an immense business on God's holy day. Now, then, friends, with the above thought in mind let us read our text:

As I passed by I beheld an altar with this inscription: TO THE UNKNOWN GOD. Whom therefore ye ignorantly worship, him declare I unto you.

Now, let me tell you as Paul told the people of Athens in olden time, "Him therefore whom ye ignorantly worship, declare I unto you." I doubt whether any tourist ever had more real enjoyment in Manitou than I found. But I found it a little unexpectedly. It commenced in God's holy temple, among Christian people, in the house of worship. You have heard my simple story, which I have told as honestly and truthfully as I knew how. Now, did any one, when under the influence of the narcotic fumes of tobacco, or through the intoxication of strong drink, or even by the expenditure of vast sums of money, ever find the happiness that I have found? Did any Sabbath-breaker ever enjoy himself so honestly and thoroughly as I have done during this Monday forenoon I have told you about? Perhaps it *is* true that we are all seeking enjoyment, myself among the rest; but has not Paul got it about right when he says, "Whom therefore ye ignorantly worship, him declare I unto you"? The Bible tells us, "*Great peace have they that love thy law.*" My testimony is, that it is true, every word of it, and there is no peace in the whole wide universe to be compared with that which comes to the faithful, honest, earnest follower of Christ Jesus.

A VISIT TO BEE-CELLARS IN NORTHERN OHIO.

ERNEST OFF ON A RAMBLE—CONTINUED.

THE topic of our conversation gradually merged into the wintering question. Of course, I asked Mr. Boardman a great many questions about the repository. To talk more understandingly we went out to look it over. Having

taken along my camera, I was prepared to take some views, and I herewith present you an outside view of the building, looking from the southeast.

BOARDMAN'S HOME WINTER-REPOSITORY.

This is double-walled, 50 x 12 feet, one story, with walls 14 inches thick. It is divided into two compartments, each of which is connected with an entryway 10x10 in the center of the building; consequently to enter the building we enter by a door at C in the diagram, not shown in cut. If desirable the door can be closed after us, and we can then enter the doors from the small entryway. The diagram below is my recollection

of the plan of the building. A is the entryway; B B the compartments; C the doorway to the entry; and D D, etc., are doors to the compartments B B, from each end of the building. W, W, W, etc., are windows, hinged in the middle in such a way that the window can be revolved to a horizontal plane, so as to allow the bees to escape. As we approached the structure, I said, "I notice that the door is open."

"It has been such an open winter that I have been obliged to lower the temperature by letting in the outside air. Besides, there are more colonies in the repository than I should prefer to have for such an open winter as the present one."

"How many colonies have you in there now?"

"I have 70 in one compartment and 100 in the other. In continuous cold weather the 100 would have been about right. But, I find that from 75 to 80 colonies in each compartment average best, all things considered. During the past winter, the compartment having the 70 did better than the one having the 100. During a severe winter the results might have been reversed."

"I suppose, it will not be possible to get a photographic view inside; that is, it will not be advisable to let in sufficient light to enable me to take a picture."

"Oh, yes! I think there will be no trouble;" and so saying he opened the end door at D; and not only that, he opened the three windows so that it was as light as an ordinary room.

"But, aren't you afraid that this light is going to disturb your bees?"

"For the length of time you require, it will do no harm."

Stationing myself at the end door D, I poised the camera and took the view shown below.

AN INSIDE VIEW OF BOARDMAN'S WINTER REPOSITORY, SHOWING FRONT ROW OF HIVES.

As Mr. Boardman has already explained in one of his articles, the bottom-boards are left on their permanent stands, and the hives, as you will notice by the engraving, are piled up in such a way that the bottom of one hive comes directly over the opening between the two below. Instead of giving full-width entrance, as most bee keepers do who winter in repositories, he gives them the benefit of a large portion of the bottom of the hive. To the stronger colonies he gives more bottom space; to the weaker he gives less. On the average there is an opening at the bottom of each hive, 4 inches wide, and the full length or width of the hive. He does not then give them the full bottom, as I had formerly supposed, and as perhaps some of the rest of the readers likewise understood.

You will notice that friend Boardman dispenses with all stringers, shelving, or any other support to hold the colonies in the repository. They are simply piled up about 4 inches apart, one upon the other, break-joint fashion.

"Now, then, friend Boardman, Mr. Newman said he did not see how you could carry hives about without bottom-boards, and yet not have the bees dropping out and flying out to make the job any thing but pleasant; and, what is more, I do not see how you do it myself."

"Why, easy enough," said my friend. Going to one of the hives (they are cleated clear around at the top, you will notice, the cover resting telescopic fashion on this cleat) he grasped its diagonally opposite corners. Leaning backward a little he let the edge of the hive bear against his person, carried the hive to the other end of the repository, set it down, took it up and put it back. He did likewise with a number of other colonies. Each one he held up, turning it up so that I could see for myself the condition of the bees, and how they apparently regarded such kind of handling.

While it looked real easy I could not be content until I tried it too.

"To prevent the bees flying out when about to remove them to their winter quarters, I am particular," he said "not to jar the hive unnecessarily, and then I prefer to have the weather just cool enough at the time so that the bees cluster a little closer than usual.

"You see," he continued, "I letter each row in the apiary, and number each individual stand. Now, when I get ready to carry the bees out I take the first hive I come to, which, in this case, proves to be F 18. Of course, I know where the F row is; and 18 I know to be somewhere about the middle of the row; and with the hive in this fashion" (holding it in the manner I have before explained) "I take a bee-line to the bottom-board having the same marking as the hive."

"But," I said, "do you think it makes any great difference as to where the colonies are put?"

"Not much, but it does some; and if I can deposit each colony where it was last fall, just as easily as not, I very much prefer to do so rather than to set them out haphazard. There is then no confusion among the bees when they take their first flight; for some old bees will be sure to know where their old stand used to be."

"I want to know what sort of a cover you put over the frames in winter."

"All the bees have is the regular hive-cover, and this they usually glue down tight; that is, I put the bees into the repository just as I find them on their summer stands, after I have satisfied myself as to their strength and amount of stores."

Now, perhaps some of our readers will begin to wonder whether those bees, during all this time when the repository was lighted as light as any ordinary room, did not become more or less disturbed, and fly out. I expected to see them fly out a great deal more than they did; but only here and there a bee would start out from its hive, and strike for outdoors. Then I said to Mr. Boardman, "You would not like to leave this compartment lighted up like this all day would you?"

"No, sir; but for a short time it does no particular harm. The few bees that fly out are old ones, rather feeble, and are not of much use to the colony. My colonies have been rearing brood quite heavily, and there is a large force of younger bees to take their place."

Glancing down to the floor (concrete cement) I noticed there were a good many dead bees. In some places, perhaps they were an inch or so deep.

"Now, it seems to me you have got a good many more dead bees as the result of your indoor wintering than we have from our chaff hives, on their summer stands."

"Yes; but," said he, "I think you will find that the bees fly out from the chaff hives in the same way. These, never returning, are lost sight of, and of course do not figure very largely in the eyes of the bee-keeper, on the death-list."

While I admitted this, it did seem to me

there were more, perhaps, than we usually lose in that way on summer stands. I say "seem," because I am not sure about this.

The dinner-hour approaching, Mr. Boardman closed up the windows, darkened them, and closed all openings except the door to the entryway A, shown in the diagram above. As we stood before the building I said to Mr. Boardman, "It is not yet quite clear in my mind whether you open that door to give ventilation or to lower the temperature, or to do both."

"Bottom ventilation to the *hive* is all that I regard as important. I open the door simply to lower the temperature of the repository."

"But," I said, "don't you have a sub-earth ventilator of some kind to the building?"

"I do not see what need I have of one. As I only want to lower the temperature, I can do it by a door or window a little better, perhaps, than to let the air become warmed under ground a little before entering the compartment."

As we were entering the house, I told Mr. Boardman that I should like to take the noon train.

"Oh, no!" said my host. "You had better take the evening train."

Having enjoyed my visit so far, it did not take very much persuasion on his part and that of his good wife to induce me to remain over a little longer. Besides, as he had promised that he would take me out to his out-apiaries I did not feel like resisting very hard. Accordingly, after dinner we went out to the barn, where Mr. Boardman had three horses, one of them being a family horse, and the other two devoted exclusively to the bees, in going to and from the out-apiaries. Very soon we were on our way, on a brisk trot, to one of his east apiaries. After going about a mile and a half we came to a piece of land belonging to Mr. Boardman. An old schoolhouse on this plot of ground had been converted into a winter repository. Like the one at home, it was an up-ground structure. The walls were 14 inches thick, and frost-proof. This building had only one compartment, which communicated with an entryway, and the latter to the outside. My friend then brought something like a dozen colonies, selected at random, out to the light, for my inspection. They were all in most excellent condition, and the weak ones seemed to be doing about as well as the strong ones. As before, I noticed dead bees on the floor, but not to the extent that they seemed to be in the winter repository at home. After closing the building we started for an out-apiary some two or three miles further east. Of course, we talked all the way. I asked him if he preferred up-ground repositories rather than a good cellar.

"I prefer them simply as a matter of convenience," he said, "in carrying bees in and out. I do not know that the bees will winter any better in one than in the other. We are now going to one of my bee-cellars under a farmhouse, where I think you will find the bees wintering as well as in either of the other repositories."

In a short time we arrived at the place in question.

"This cellar," said Mr. Boardman, as he opened the door, "is one that I partitioned off."

As before, Mr. Boardman and I examined the colonies at random, and found them to be in good condition.

"Now," said he, "here is one colony that I put in by way of experiment. I do not know how they will winter. It was very weak, and I thought I would put it in just to see how they would winter."

Turning the hive up we could detect no signs of life. He set the hive down again and lifted up the cover, and, lo! every thing was as still as death. When I came to examine the size of the colony I was not very much surprised myself. There could not have been very many more than 200 bees, even at the outside, in the cluster; but the evidence seemed to point to the fact that they had only just died.

"Ordinarily," said my friend, "we unite such weak ones; but as a general thing we can winter weak colonies—that is, if not too weak—as well as we can strong ones." After putting the hive back in its place, he continued, "You will notice the cellar is very dry. Some bee-keepers claim that they could winter bees in a cellar 'reeking with dampness,' if only the food were right. I am not so particular about the food, but I am particular about a dry warm place."

All of Mr. Boardman's bees, as he subsequently told me, were wintered on whatever stores they happened to have in their hives. If the food is well ripened, the colony not too weak, and the cellar dry and warm, he does not worry very much over probabilities. While he can and has wintered bees on honey-dew he prefers the nectar of the flowers. As we stepped out of the repository Mr. Boardman said, "Here at this apiary I employed an inexperienced boy. I should have had more money in my pocket had I paid him the wages I did and had him stay at home. He made enough muss and trouble to more than offset all the good he did."

Mr. Boardman prefers a man grown—one with sufficient maturity of judgment to do what he is told to do.

To be Continued.

RECENT DEVELOPMENTS

CONDUCTED BY ERNEST R. ROOT.

THE DOVETAILED HIVE

A GOOD many suggestions concerning the new hive have come in. One or two of the friends think that plain ordinary box joints will answer all practical purposes, and that the dovetailed corner is just so much more useless expense. Having perfected special machinery, the item of dovetailing is a very small one indeed in the construction of the hive, and the attendant advantages are too great to be ignored. To test the strength of a dovetailed corner we drove one hive together *without paint or nails*, and found it was nearly as rigid as a *Simplicity nailed*. Again, we drove together the dovetailed

body, having previously dipped the dovetailed edges into some thin paint. The hive was then allowed to become thoroughly dry. To test its strength I then put my whole weight, 150 pounds, upon it in such a way that the pressure was exerted on the diagonally opposite corners. I then pounced it upon the floor, balancing myself milk-stool fashion. I presume that something over 200 pounds upon the opposite corners was exerted before I could hear any thing crack. Mind you, all this was *without a single nail*. But on account of the daubiness of paint, our man prefers to nail them together and then cross-nail. It is impossible to cross-nail an ordinary box corner—that is, where one board simply laps across another. A cross-nail joint is very much superior in point of strength and durability to the plain box corner.

There are some people who will be sure to get a hive together wrong if there is a possibility of getting it so. For instance, with a box or lap joint they will lap the end across the end of the side, or vice versa, when the opposite is intended. Carelessness in this respect results in the wrong inside dimensions of the hive as a matter of course. With the Simplicity or with the dovetailed corner, such a thing is impossible. You may say that a man of ordinary common sense ought not to do such a thing. Some very foolish blunders are made, as we know from experience, by some of our customers.

If there is any warp in a side or end, the dovetail, when driven together, will take it out, and prevent any further trouble from that source. No, sir, the dovetailed corner is considerably better than a box joint.

As announced in our last issue, I here-with present the modified engraving of the Dovetailed hive as we now make it.

THE DOVETAILED HIVE.

The principal change noticeable on the hive will be the changing of the bee-space to the top of the brood-frames, instead of at the bottom as before announced. You will notice what a good-sized entrance we allow. By the accompanying wood-engraving you will see the construction of the bottom-board.

BOTTOM BOARD.

It is simply a cover-board, hardly good enough to be used for a cover, cleated at both ends like a cover, with a quarter-inch strip nailed on each of its two sides. One of the end cleats is leveled down, so to speak, to allow an entrance-way. This bottom-board can be used for a cover, but the cover can not be used very well as a bottom-board. In general, the construction of the hive is now such that, in whatever combination it may be made, a

bee-space will always be between each separate compartment; and if desired, the honey-board may be omitted, although I should never advise it.

Some of the good friends think we are making a mistake to leave out the tin rabbits. The new hive is intended for comb honey and not for queen-rearing. Where the frames are to be handled often, I would recommend using the Simplicity hive with the tin rabbits.

SECTION-HOLDERS.

There has been a large demand in the last few days for the Dovetailed hive; and with scarcely an exception the section-holder arrangement for surplus is chosen. For the new hive I feel quite certain that it is the better arrangement, although personal experience this summer may modify my views.

Right here I will make an extract from a letter of our friend H. L. Jeffrey:

Those frames for the sections will do two things for the boxes; first, keep them clean, and save, in time of cleaning, more than the cost of the frames. Second, by keeping the outer end of the sections of a higher temperature than with only one thickness of wood, and getting those sections filled out more like the center ones, flush with the edge of the section, the same result will be found by making your crates with a division-board inside, with an $\frac{1}{8}$ -inch lag strip to give the section more space, and keep up the evenness of the heat. That is what 10 years' use of double sides has shown to be true. Mr. Alban Ferriss has used those topless section frames for years, and so have a score of others that I know of. From what I have used of a similar fixture, and seen by a score of others use, I am sure you are putting out the best thing that you have had yet, although it is a new combination to the public, of old things.

H. L. JEFFREY.

Marble Dale, Ct.

You will notice that Mr. Jeffrey says that Mr. Ferriss and a score of others have used these frames and like them; and he, Mr. Jeffrey, thinks we are putting out the best thing that we have ever before advertised.

I also make an extract from our friend Mr. Stachelhausen, who, it will be remembered, produced 11,000 pounds of comb honey last year, when a great many others failed. He says:

The super is ingeniously constructed, and the section-holder seems to me to be a noble arrangement.

Our section-holder super-shells are just $4\frac{1}{2}$ inches deep and $18\frac{1}{2}$ inches long, inside measure, and this is too deep and too long to accommodate $4\frac{1}{2}$ sections; but by a little calculation you will see that it is just right for a T super to accommodate sections $4\frac{1}{2}$ square, $1\frac{1}{8}$ inches wide, which we regularly keep in stock. I mention this fact, because some complain that the $4\frac{1}{2}$ sections are too small; and while I would not advocate changing to the larger size of section, yet if the purchaser adopts the section-holder arrangement he can easily convert it into a T super by using the $4\frac{1}{2}$ sections, as stated; but if he orders the T-super arrangement he can not change it to any thing else.

For those who desire to use the T super and $4\frac{1}{2}$ sections, we make the ends thicker and the holder-shell $4\frac{1}{2}$ inches deep.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, OHIO.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, APR. 15, 1889.

Thou shalt love the Lord thy God with all thy heart, and with all thy soul, and with all thy mind, and with all thy strength: this is the first commandment.—MARK 12:30.

CAPTAIN HETHERINGTON'S ARMY LIFE.

In another column will be found an exceedingly interesting account of the army life of that bee-keeper and soldier, Captain J. E. Hetherington. As one who manages successfully some 3000 colonies, we extend to him our hearty congratulations; and as a soldier, we feel sure that the whole bee-keeping fraternity may well feel proud of him, whether North or South.

THE VIRGIN-QUEEN TRAFFIC.

The following, from the *Review* for March 10th, is so exactly in line with our opinion and experience, that we think best to place it before our readers:

Mr. Jones favors the traffic in virgin queens. That they can be furnished very cheaply, there is no question; but that they are difficult to introduce, we know from experience. A newly hatched queen is easily introduced. As the hours go by, the probabilities of acceptance are lessened. With us, the percentage of loss has been great when the queens were three or four days old. Then there is the risk of loss in mating; and, unless the locality of the purchaser can furnish excellent drones, the queens will find undesirable mates; and as prepotency is on the side of the male, there will be little "value received."

IS THERE A BETTER BAKING POTATO THAN THE SNOWFLAKE?

You may remember that, on page 191, I asked for samples of the best baking potatoes known. Well, I received from George Ebell, of Baker City, Oregon, four Early Rose potatoes, by express. The four potatoes weighed 8 pounds. They were very good, but hardly equal in quality to the Snowflake. He writes as follows:

I raised them on friend Terry's plan. I have several thousand pounds as large as the sample sent. I held 50 pounds in one arm.

Baker City, Oregon, March 23, 1889.

GEORGE EBELL.

Peter Henderson's Early Puritan comes so near the Snowflake that it might almost be said to equal it; and as it is said to be as early as the earliest, and as productive as any of them, we are inclined to consider it an acquisition. We are now planting it, largely with a view of furnishing seed to our subscribers next year.

THE EDITORIAL "I" IN GLEANINGS.

I SUPPOSE that most of our readers are aware that the coarse print on our pages is all written either by Ernest or by A. I. Root. Well, now, although Ernest and A. I. agree pretty nearly on most points, it begins to be apparent that our opinions do not always coincide exactly. The same is true in regard to the A B C book. A large part of the last edition was written by Ernest himself; and if you should find that I express an opinion in one place and Ernest gives a conflicting opinion somewhere else, please do not quote it as an illustration of A. I. Root's inconsistency. In many things, especially those pertaining to the bees, Ernest has had

more experience at the present time than I have had; and, in fact, when some one comes to me for an opinion, I very often turn him over to Ernest because I have more confidence in his decision than I should have in my own. The matter of gardening and raising crops is, however, more especially my province.

CAPTAIN HETHERINGTON'S LOSS.

JUST as we go to press, the following sad intelligence comes to hand:

The readers of GLEANINGS will deeply sympathize with Capt. Hetherington and wife in the loss of their youngest son, John Edwin, who died April 3d, aged 4 years and 3 months. Although so young, many had observed that his remarkable intellectual development, together with an unusual degree of self-reliance and energy, gave promise of a life of great usefulness. P. H. ELWOOD.

Starkville, N. Y., April 9, 1889.

We extend our sincere sympathy to the captain and his wife.

ORANGE-BLOSSOM HONEY; THE FIRST EXTRACTED HONEY OF THE SEASON.

We are in receipt of a sample from Florida, with the following letter:

Mr. Root: We extracted our first honey March 21, taking out five gallons of mixed honey, fair and good. Monday, April 1, we extracted again, and got 30 gallons of as fine orange-blossom honey as could be desired, a sample of which I send you. We will extract again next Monday, and expect to get 30 gallons more then, of the same honey, and that will close orange-blossom for this year. We have 30 colonies. If we have no disappointment, the season will last 3 months. Our bees are on the St. John's River. JOHN CRAYCRAFT.

Altouna, Fla., Apr. 3, 1889.

I am happy to say that the sample of orange-blossom honey sent us is perfectly delicious, and ought to bring as good a price as any of our clover or basswood. I think I should place it at the head. The flavor is quite similar to that furnished by the Baldensperger Bros., of Jaffa, Syria, noticed in these pages some two or three years ago. What will you take for a barrel of it?

TO WHOM IT MAY CONCERN.

We have of late been receiving so many communications from people who have invested money in a patent-right pruner, claiming to have purchased the territory of our agent or agents, that we wish it distinctly understood that we have no agents, and never did have, for selling rights for any patent. Whoever claims to be our agent, or to be authorized by us to sell rights for any pruner, is a humbug and a swindler, and we hope that all good men will assist in putting down this fraud. In some cases poor widows have scraped up their scanty earnings to pay for a county right, only to be informed, when they write to us, that their money is worse than thrown away.

THE ILLUSTRATED HOME JOURNAL.

THE above is the title of a monthly periodical published by T. G. Newman & Son, editors and proprietors of the *American Bee Journal*. This new journal was formerly known as the *Chicago Illustrated Journal*. After three volumes were issued, it was voluntarily suspended for a time. An auspicious time having arrived, the editors decided to renew its publication, changing its name slightly as above. It is printed on nice calendered paper, and contains 36 pages, including a tinted cover. It is well illustrated, and the initial article is entitled "One Hundred Years a Nation," by the editor. Mr. Newman is a man acquainted with men and with the times, and the article is comprehensive and complete. We wish the publishers every success. Those of our readers who would like to see

how good an illustrated home journal can be had for \$1.50 per annum can obtain a sample copy by addressing T. G. Newman & Son, 923 West Madison St., Chicago, Ill.

LOOK OUT FOR HIM.

J. H. BREWER, physician and surgeon, Jackson, Neb., wrote us as follows, Oct. 11, 1888:

Please send me one copy of your A B C of Bee Culture and one of your best bee-smokers, by express, C. O. D. J. H. BREWER.

Jackson, Neb., Oct. 11, 1888.

Judging that the want of the goods was probably more than the worth of them, we sent them right along with above instructions. When notified they were not taken from the office, we wrote the doctor; and as he did not reply we wrote again, telling him we should be \$1.05 out of pocket if he did not take the things from the express office according to promise, the above amount being the express charges both ways. We even wrote the third time, telling him we had his plain order in black and white, with his signature at the bottom; also telling him that we should feel it our duty to caution others among the bee-fraternity against trusting him in a similar way, if he did not respond. We also took pains to find out that he was in his usual good health, and abundantly able to answer letters, even if he could not raise the small sum of \$1.05. As he makes no reply, we publish him as above.

A BOOK ON BUCKWHEAT WANTED.

SINCE the advent of the new Japanese buckwheat, the industry has assumed such proportions that it is quite important that we have the fullest information in regard to preparing the ground, sowing the seed, use of fertilizers, harvesting, cleaning, and, in short, every thing connected with the raising of buckwheat. The matter of getting another crop in, after something else has come off, is also of much moment. My experience with the articles on sweet potatoes has opened my eyes to the fact that the readers of GLEANINGS are able to furnish a valuable treatise on almost any new industry. Now, friends, please tell us what you know about buckwheat, and we will have a "buckwheat issue" some time before it is time to sow the seed. I will pay for your communications what I think I can afford to, as I did with the papers on sweet potatoes. We want all the valuable facts and hints we can get. If some of them do not occupy more than ten lines, all right. Let us have them, and we will pay you something for your trouble. Now, please remember that we want facts from actual experience, and experiment rather than flowery essays. If some one of our readers has raised buckwheat to the extent of a thousand bushels or more in a season, we should like to have a pretty comprehensive article from him; but as there will necessarily be much repetition, most of you had better make yourselves as brief and comprehensive as you can. We want the facts boiled down. Where one raises only a little patch, the question comes up about harvesting. He can not afford to get a thrashing-machine. Shall he then load it on wagons and draw it to some machine already set up? or shall he thrash it with a flail? Has anybody yet raised two crops in one season? and does it yield grain in any locality when sown early in the spring, as soon as frost is out of the way? How about the use of chemical fertilizers? Shall we sow it broadcast, or with a seed-drill, etc.?

SPECIAL NOTICES.

HENDERSON'S EARLY PURITAN POTATO.

We have just purchased a barrel of these to plant, and we will furnish eyes, by mail, at the following prices to those who want them: 10 eyes, 15 cts.; 100, 75 cts.

EARLY OHIO POTATOES FOR PLANTING, AT A BARGAIN.

While our stock lasts we will furnish Early Ohio potatoes at the same prices as Beauty of Hebron and Burbank were offered last month; namely, 50 cents per bushel, or \$1.25 for a barrel of three bushels.

EXCELSIOR FLAT DUTCH CABBAGE.

When we started out with our seed catalogue, you know we decided to have only a few of each kind of vegetable. I think we had at first four kinds of cabbage. Our list has now, however, run up to seven, and it does not seem as if we could drop any of them. Worse still, there are several complaints that we have not in our list a late flat Dutch cabbage; we have therefore added Excelsior Flat Dutch. Five cents per packet; 15 cts. per ounce, or \$2.00 per pound.

FIGWORT, OR SIMPSON HONEY-PLANT ROOTS.

In consequence of my absence in California last season, our rich market-gardening ground was not plowed in the fall, and, as a result, great numbers of figwort plants came up and became strong enough to winter over. If orders are sent in at once we will furnish these roots as follows: 10 roots, 15 cts.; 100, 75 cts.; 1000, \$5.00. If wanted by mail, add 8 cts. for 10, or 50 cts. for 100, postpaid. They are just as sure to grow as a potato or horseradish root, and will blossom profusely this present season.

IGNOTUM TOMATOES.

It is probably now too late for most of you to sow the seed and get plants to bear a crop. Now, we can not give away the plants as we have done with the seeds, but we will send you three nice plants, packed in a wooden box, for 10 cents; or 10 for 25 cents, by mail, postpaid. By express the price will be \$2.00 per 100. We have now in our greenhouses a splendid lot of vegetable-plants of all kinds. For prices and particulars, see our spring catalogue of plants and seeds, mailed on application. As a sample of our ability to send plants safely long distances, see the following:

Mr. Root: I bought ten Mikado tomato-plants of you last spring; and, to say the least, they far exceeded my most sanguine expectations. They were not wilted in the least when I received them, and I realized between four and five bushels of large, beautiful, thoroughly ripe tomatoes from the ten plants. I raised three varieties of tomatoes last year, and the Mikados were the only ones that ripened thoroughly. This year I am going to buy fifty plants of Mikado from you. Will you please let me know the price of the same?

Belmont, Wis., April 4, 1889.

J. HARRIE MORRIS.

THE A B C OF CARP CULTURE.

The above book is finally ready to mail. As it is almost two years since the fore part of it was printed, it ought to be well done. Our readers will understand that a great part of it is a reprint of George Finley's book, entitled "German, or European Carp." Friend Finley accumulated material for it for three or four years, and I then paid him \$200 for the right and title to the original book, together with what he had done on a new edition. After I had worked on it for about a year I found that my many cares made it almost out of the question for me to sit down and sift the chaff from the wheat as I felt ought to be done, and I therefore put the whole thing into the hands of our good friend Dr. C. C. Miller, who gave his whole time and attention to it for several weeks. Altogether we think it contains all that is valuable up to date on carp culture. As with our other books we propose to add to it, in the way of an appendix, every thing new as it comes up. The price of the book is 35 cents; by mail, 40 cents. The original book was \$1.00, and we have made it contain double the amount of matter, and illustrated it with many fine engravings, and yet sell it at only 35 cents.

KIND WORDS FROM OUR CUSTOMERS.

Goods came to hand all O. K. Thanks for promptness. Thank you for Christmas gift, biographies. Moltke, Tenn., Jan. 14, 1889. S. L. MEDEIN.

I have two plants of your white lettuce growing, which I prize very highly. Mrs. A. A. NEEDHAM. Sorrento, Fla., Jan. 17, 1889.

The seed I got of you last year were all satisfactory; the cabbage, especially, headed uncommonly well, and is a fine quality. WM SCHWAAB. Nashotah, Wis., Feb. 16, 1889.

I am glad you are sending me GLEANINGS. I used to think I could not afford to take it, but I think I have lost a good bit by not taking it long ago. CHARLES CHANDLER. Pennsville, O., Feb. 9, 1889.

You "beat the Dutch" for promptness. The goods I ordered of you on the 9th arrived on the 12th, and in fine condition. I did not expect them before the 15th. My neighbors are well pleased with their sweepers. Accept my thanks for your promptness, also for your letter of advice. Peachville, Pa., Mar. 23, 1889. C. A. LEWIS.

MRS. HARRISON'S ORPHANS, AND THE STORY OF THE BIBLE.

The orphans enjoy the Story of the Bible very much indeed. Katie reads, while Lucy peeps over her shoulder to see the angels. The style is simple and easy, and real fascinating to young people. Peoria, Ill., Feb. 11, 1889. MRS. L. HARRISON.

I would no more think of doing without GLEANINGS than some other necessity. Your trip to California did me more good than any other description of the country I ever read, because I know you are truthful. W. McDOUGAN. Santee Agency, Neb., Jan. 15, 1889.

I wish to congratulate the editor on the improvements made in GLEANINGS. It grows better and more interesting with each issue. I hope the editor may long continue in the good work, and be well paid for it too. Prospects are good for another year. J. B. RIGGENS. Swanton, Neb., Feb. 18, 1889.

I have received your A B C, and am proud and happy to get such a beautiful book as a present from the author. I have read most of it, and like it better than any of the other bee-books I have seen. You should be happy to be able to give so much for so little money. I have your picture and biography in the book with the others taken from GLEANINGS. J. F. MCINTYRE. Fillmore, Cal., Jan. 7, 1889.

I am very much interested in your Notes by the Way, especially that concerning David C. Cook. We have used in our Sunday-school for about 15 years, his literature. I was very much surprised at his prosperity, when I think of the difficulties he had to surmount, in the way of other publishing companies, etc. We think GLEANINGS the paper any way. E. R. A. and B. BRAINARD. Postville, Ia., Jan. 21, 1889.

Mr. Root:—At a meeting of the Peoria Scientific Association held last evening, a very cordial and unanimous vote of thanks was extended to you for the beautiful and valuable volumes which found their way to the museum last week, as well as for the Feb. No. of GLEANINGS. I assure you we are deeply grateful to you for these favors. The books are of incomparable value to one who is interested in the subject of bee-culture, and I shall take pleasure in recommending them to my friends. Peoria, Ill., Feb. 9, 1889. M. LOUISE WHITE.

GLEANINGS AND THE TRAVELS.

Friend Root:—"Beeology" does not awaken the same interest with me in winter when my bees are at rest as in summer when their music is heard in every quarter; yet GLEANINGS has always been a welcome visitor at my "news-table" since I first formed its acquaintance, and especially so for the

past few months, as I read the description of your journey to the Pacific coast. I am quite familiar with the route you traveled. I took the same journey in 1882, but went much further, and did not stop till I landed on a branch of the McKenzie River, near the head waters of the Youcan.

J. F. CALLBREATH.

White Lake, N. Y., Jan. 21, 1889.

The bill of goods came to hand in fine shape, and such a handy package! I would advise all ordering small goods to have them rolled up in perforated zinc.

A. A. PARSONS.

Avon, Ind., March 18, 1889.

The seeds and cutlery I ordered of you came all right in due time. The plated knives and forks are splendid—about a third cheaper than we could get them here; and the pocket-knives are first-rate for the money. Please accept thanks.

Morristown, Ind.

MAD. TALBERT.

GLEANINGS CONSTANTLY GROWING BRIGHTER.

Notes of Travel prove very interesting reading. GLEANINGS constantly grows brighter and better. Its artistic beauty is a joy forever. Long live GLEANINGS and its energetic editor.

Gallinas, Texas, Mar. 11, 1889. W. A. MCPHAIL.

Strawberry-plants received all right. Many thanks for your promptness. I do think they are the finest-rooted plants I ever saw, and the best packed and put up. I showed them to a nurseryman, and he said he had been shipping plants a good while, but he never could put them up as those were.

Hickman, Ky., March 19, 1889. J. O. BARNES.

While kind words are pouring in to GLEANINGS and its publisher, let me say a few words for one, a supply-dealer brought before us by the help of GLEANINGS—J. M. Jenkins, Wetumpka, Ala., a man who not only tries to satisfy his customers, but does it.

S. C. CORWIN.

Sara Sota, Fla., Feb. 28, 1889.

The new Langstroth is received; very creditable to the reviewers. Though retaining the fine flavor of the original work, all that was essential and characteristic, it has much new matter, and is up to the times, and worthy of a double star in your catalogue—a remarkable production, with all the attractiveness of a new book.

D. F. SAVAGE.

Hopkinsville, Ky., March 11, 1889.

PLEASED.

I received the goods you sent me, in good order. The Little Detective scales is a beauty, and weighs accurately. The 554 sections are good enough for me. I ordered only 500. The foundation is the best I ever saw. I want to say, also, that GLEANINGS is a welcome guest, and read with interest. Our Homes is the best of all. Leave that and the Tobacco Column out, and I don't think I would renew.

W. A. WILLIAMSON.

Friendly, W. Va., Feb. 11, 1889.

THE NOTES OF TRAVEL.

I greatly enjoy the Notes of Travel. They give me the California fever even more than I had it when I went there to spend the winter of 1885. The biographical sketches are also very entertaining. It is a pleasure to see what a number of the best bee-keepers are Christian people. The past season has not been very good. I began the season with 182 colonies in three apiaries, and secured about 2500 lbs. of honey. Though this is little, my neighboring bee-keeping friends did not do as well.

Edinburg, O., Jan. 23, 1889. C. R. BINGHAM.

Through your kind indulgence I have enjoyed (I should have said we have enjoyed) the visits of GLEANINGS for about three-fourths of a year on tick. But I have the money now, and I herewith forward it to you. We have nearly decided notwithstanding our bees do poorly, that we can't do without GLEANINGS from other considerations—the children say, especially if you take any more California trips. We like the tone and spirit of its comments and editorials and—its sermons.

Fullerton, Neb., Jan. 20, 1889. J. E. FAUCETT.

OUR SOLAR-WAX EXTRACTOR, AND HOW IT WORKS.

The goods ordered Jan. 16 came to hand Feb. 9, all in good shape. I couldn't eat dinner till I saw inside that wax-extractor, and then it fairly took my appetite. I couldn't rest till I saw whether it would melt wax, and so I set it out by the side of the smoke-house, and put in some old tough combs, and in a very few minutes they were melting into the nicest wax I ever saw. It astonished even the natives.

ALLEN BAGLEY.

Siloam, Ark., Feb. 10, 1889.

THAT VISIT TO CALIFORNIA.

Friend Root:—I see on page 164, that Messrs. Osburn and Gilchrist have expressed their dissatisfaction or disappointment, caused by your not making them a visit while you were in California. I do not think that you were altogether at fault, and I should not be surprised if there were many more whom you missed, making such a flying trip as you did. When you called on your humble servant he was away from home, and you drove nine miles to see him. Although we had but a two-hours' chat, yet I shall never forget it. I am glad to know that you are planning another journey, and that Mrs. Root (and Huber) are coming with you. I wish you to be sure to call and see me. This time I shall try to be "at home," and have my "Dickens curiosity shop" in a little better order, and perhaps have something more inviting than "bachelor's hall," unless you come too quickly.

W. W. BLISS.

Duarte, Cal., Mar. 19, 1889.

GLEANINGS AND ITS POLICY.

The seeds and sample squash-boxes, feeder, etc., came to hand, all right, and the express was only \$2.75, which was not more than I expected. I hope I shall get a few more subscribers for GLEANINGS, for I think it not only a good bee-paper, but a good paper to have around. In these days, when the "almighty dollar" seems to take the first and almost last place, in most people's minds, even Christians', it is very refreshing to take up a business paper that brings before the minds of its readers constantly that whatever we do should be done in the name of the Lord Jesus. To take up a fruit or bee paper that takes up a large part of its space in throwing dirt, or in private squabbles, is not edifying or profitable; and while I would express my views and opinions as distinctly and impartially as I could, I would also be willing they should do the same; and if they did knock some of the corners off my pet hive, I would not think it necessary to bite their heads off for doing so. I had begun to think, before I got hold of GLEANINGS, that most bee-men were about as waspish as their hybrids, which are not a very charitable conclusion to arrive at; but I must stop, for this is your "busy day." I generally think of you as the busy man, till it makes my head swim.

THOMAS SLACK.

Waterloo, P. Q., Mar. 18, 1889.

PRICE LISTS RECEIVED.

Since our last issue we have received price lists of queens, bees, and apiarian supplies in general, from the following parties, who will be glad to furnish them to applicants. Those marked with a star (*) also deal in fine poultry.

J. H. Larrabee, Larrabee's Point, Vt.

Berlin Fruit Box Co., Berlin Heights, O.

W. E. Clark, Ori-kany, N. Y.

S. W. Morrison, Oxford, Pa.

J. W. Bittenbender, Knoxville, Iowa.

J. N. Colwick, Norse, Texas.

Martin & Macy, North Manchester, Ind.

We have just printed for Elijah Debusk, Friendship, Va., his annual list of bees and supplies.

J. W. K. SHAW & CO., Loreauville, Iberia Parish, La.

We have, ready for mailing, 100 large, light, tested Italian queens, imported mother, Sept. and Oct., 1888, rearing, very fine, at \$1.50 each. Untested, \$1.00; per doz., \$10.00. Send for circular. Money orders, New Iberia, La.

Glass Honey Tumblers and Pails.

Glass Tumbler. Nos. 788 and 789. Screw-top Pail. Nos. 775 to 778. Oaken Bucket Pail.

Above we present our three staple styles of glass honey-packages for this season. We are unable to get any more of the screw-top glass pails, shown in our catalogue, such as we have been selling for a number of years, and we have substituted in its place the one shown in the center above. We have this made specially for our trade, and no one else handles it. The following revised table of prices takes the place of those in our catalogue. Please notice important changes, and please be careful to be specific in telling what you want when you order. Give the quantity, number, name, and price, to avoid mistakes.

TABLE OF PRICES—NO CHARGE FOR PACKAGES.

Please order by number and name, and give price.

Number and Name.	Capac.	Price.	Barrels.
No. 778, 1-lb. tumbler.....	10 oz.	3 28	2 50 250 85 30
No. 789, one-pound tumbler.....	16 oz.	3 30	3 00 200 5 20
Nos. 788 and 789, nested.....		6 57	5 25 200 9 00
No. 775, 1-lb. screw-top glass pail.....	11 oz.	5 40	3 50 250 7 30
No. 776, small pound screw-top pail.....	14 oz.	5 42	3 75 200 6 60
No. 777, large pound screw-top pail.....	17 oz.	6 32	4 75 150 6 60
No. 778, 1-lb. screw-top glass pail.....	24 oz.	7 65	6 00 100 6 60
1-lb. Oaken Bucket pail.....	10 oz.	5 42	3 75 200 6 60
1 lb. Oaken Bucket pail.....	16 oz.	5 45	4 30 150 6 10

In lot of 5 barrels, any one or assorted kinds, 5% discount. Please notice these points in the table above.

1. The capacity as given is what each will hold, well filled with honey of good consistency.

2. The price of one, 10, and 100 is given in the first three columns; the fourth column gives the number in a barrel, and the 5th column the price of a barrel.

3. Notice that it is much the most economical to buy them in barrel lots, if you can use so many. The reason for this is, that all manufactures of glassware have a uniform charge for packages, and a barrel has the largest capacity for the price of any thing used. Every barrel, large or small, costs us 35 cts.; a box, holding only half as much, costs the same. Thus by taking the largest barrels, well filled, we can give you the most value for the money.

4. We can not break packages of 100 or barrels at the price of a full package.

5. The most skilled packers are employed, and goods are delivered to transportation companies in good order; we will not, therefore, be responsible for any breakage.

Send your orders early, while we have plenty of stock and can maintain above prices.

A. I. ROOT, Medina, O.

OUT-APIARIES—NO. VI.

ENGAGING SOME ONE TO HIVE SWARMS.

IF you expect some one of the farmer's family at the out-apiary to hive swarms for you, the matter of compensation should be agreed on in advance. As to what this should be, it is just as hard to say as it is in the matter of rent. On page 946, GLEANINGS, Dec. 15, 1887, are answers to the question, varying from 10 to 75 cts., Dadant & Son paying the latter price for hiving each swarm. Turn to page 9, Jan. 1, and read the very interesting article from C. P. Dadant, after which you will agree that, in their case at least, they are not so far out of the way in paying such high prices for rent and for hiving swarms. They have very few swarms, and they expect them to be hived by a man who has judgment to hive them in good shape, so they consider it a matter of policy to pay a good price for the few that do come out. If only one swarm comes out in a day or two days, you can well afford to have them hived at a cost of 75 cts. rather than have them go off. If, however, you have an average of 6 swarms per day, a man could make very fair wages at 25 cts. each, or \$1.50 per day, especially as the swarming does not continue all day long. Another thing that might make a difference, is the surrounding timber. It is one thing to hive a swarm from a low apple-tree, and quite another if the swarm hangs on the top of a tall forest-tree. In some cases it may be the better way to pay some one a fair price by the month or week. There is, however, an advantage in paying by the swarm, for then the one employed will be more sharply on the lookout not to let a swarm get away. There are, however, some who are so faithful that they will keep just as close watch, whether paid one way or the other.

In any case it is a good plan to pay so well that the one employed may feel a pleasant interest in the work.

If your queens are all clipped, then there may be less labor; but if the swarms are hived, fully as much intelligence is needed, but they may be managed in such a way that no hiving will be needed. I never had any one watch for swarms for me in an out-apiary but one summer, and then I had a young lady watcher, of little physical strength, but bright, and exceedingly faithful. When a swarm issued she immediately looked for the queen, which she rarely failed to find, caged it, and put it where the bees of the colony could take care of it, then wrote down in a memorandum-book the number of the colony and the date of issue. When I came to the apiary some time within every three to five days, she submitted to me her memorandum and gave me a full history of any thing unusual that had occurred.

LAYING OUT THE APIARY.

After you have made such an agreement that you think there will be no chance for any disagreement in the future, look your ground over carefully and decide just where you will place your hives, and it will be well to get every thing ready in advance so far as you can, so that, when your bees are brought on the ground, the hives can be set directly in their places. As I am trying to tell especially what is appropriate for those to know who have had no experience in out-apiaries, it is perhaps not appropriate for me to say much about the matter of arranging apiaries, for my readers are supposed to have experience in such things; but a little in that line may do no harm. It is desirable, if possible, to be able to drive quite close with a wagon, so as to load and unload hives, etc., conveniently, and I should like to have the place for driving up at the back of the hives, if it can easily

be so, in order that the flying bees may not find your horse in their line of flight. Of course, if your hives face in opposite directions, as is sometimes advisable, it may not be possible to get very near without getting in the way of the bees.

CHEAP ARRANGEMENT FOR BEE-STANDS.

The lay of the land may have something to do with the order in which the hives are placed; but whatever the arrangement, let your distances be accurately measured, and let every stand be leveled in one direction with a spirit-level, so there shall be no danger of combs hanging out of plumb. I like a very cheap stand that can be easily leveled, costing so little that I can afford to let it stand the year round, and thus avoid measuring and leveling each spring. Take two pieces of fence board or other board, long enough to hold two hives (if you don't want your hives in pairs let the boards be short enough for a single hive); lay them parallel on the ground, and level them, letting one be enough lower than the other (an inch or so) to allow the hive the proper pitch forward; then lay, across these, loose boards, that may be old, long enough to accommodate the hives.

C. C. MILLER.

Marengo, Ill.

I agree with you, friend Miller, that, after a stand is once leveled up, and fixed as we want it, we can not afford to move it and have to go over the same thing again. Now, in the stand you describe and illustrate you do not say that any part of it projects beyond the hive; but I am afraid, from the looks of the picture, that it does project; and one of the first things I decided vehemently in bee culture was, that no bee-hive should ever stand on a board, stick, or any thing else, that visitors might step on. I need hardly tell you why. A great many times in visiting apiaries—that is, apiaries belonging to a certain class of people, I would find the hive sitting on a board or stick. After the grass has got so high as to conceal the board from view, somebody comes along and steps on one end of it, and the hive is tilted. Of course, they will not have presence of mind enough to get away until the bees are out in force to resent the insult. Another thing I decided on was, that there should be no holes under the stand where toads, spiders, snakes, or any thing else, could hide. Our chaff hive has no stand at all, as you know; and the Simplicity has none except the cover that is used as a bottom-board, and this is set on four half-bricks; and may be your stand is just as good as that everlasting Simplicity top or bottom board. But I have had my say about it, and the friends and yourself and the readers of GLEANINGS can now fix theirs as they have a mind to.

RAMBLE NO. 15.

A SWA-REE.

SEEMING much, recently, in the journals about I, We, Us & Co., the Rambler will say *we* after this. Somebody has said that *we* meant himself and his wife. All I have is my pony Nig, and Nig and I are together much of the time, so *we* means the man and horse in our case.

A hardware merchant, an enthusiastic amateur bee-keeper of Whitehall, had called upon the Rambler many times, and, in answer to many pressing invitations, one bright August afternoon found us at Mr. McLachlin's home. Whitehall is at the head of navigation on Lake Champlain, and also at the head of the raging Champlain Canal. The village presents the appearance of some of those Alpine villages in Switzerland, which the Rambler has visited (in his dreams). Streets run on terraces above each other, and many a gorge and rocky nook surprise the traveler. I found Mr. McL.'s residence surrounded with outcropping rocks, and in the rear of the house a rocky nook surrounded with evergreens, and provided with rustic seats and tables, which at the time seemed to lie around in some confusion. Mr. McL. explained that a swa-ree the evening previous had disarranged things. The Rambler was upon the point of asking what was the nature of a "swa-ree," when it occurred to him not to expose his ignorance before cultivated people, thinking he would pick up from conversation whether it meant swarming bees or something to eat or drink. We were just so tickled that we held our tongue (Nig and I), for Mrs. McL. then and there suggested that we have a swa-ree after tea. We (Nig and I) said we would help to the best of our ability.

Mr. and Mrs. McL. had a fine family circle of children, from a babe in the cradle to a boy eight or ten years old, and we were pleased to note with what care all questions were answered and correctly explained, and how bright and intelligent the children were, and interested in every thing the parents were. Church, Sunday-school, day-school, the bees, poultry, the cow, horse, and flowers, were all subjects of conversation. The careful answers to their many questions led them to put implicit confidence in the parents, and it was a beautiful home and family, so much in contrast with many a sad home in which the Rambler has been.

After tea, all prepared for the swa-ree; and the Rambler was in a sweat of consternation to find that the leading part had been assigned to him. To find relief we went out by the back door and interviewed the hired girl. As a leading question, we (Nig and I) asked her if she was fixing for the swa-ree. Said she, "Arrah, now, mon! go along wid yees. I niver shwore in my loife. It's a purty question yees be axin me—me, a mumber of the Catholic church, and to-morry the day of confission—out wid yees!" Investigation didn't proceed further in the direction of hired girls with bandy dishcloths and broom-sticks. We went around the house and found the whole family, including the cat and dog and some of the neighbors, seated on the lawn near the bee-hives, and Mr. McL. said he wished me to conduct the swa-ree by explaining various matters of interest in a bee-hive.

"Well," said we, mentally, "if that's a swa-ree, the Rambler is at home." We explained that if

was late in the day to examine bees, but we would try not to rouse them too much. Mr. McL. sat down on the wheelbarrow and said his bees were very gentle, and told us to go ahead.

Upon opening the hive, it was evident, from the way things were glued, that the combs were seldom manipulated. A good amount of smoke enabled us (Nig and I) to get out the frames, make various explanations, and answer a whole volley of questions. The queen was luckily soon found and exhibited; also drones and drone comb, queen-cells, etc. It was solid interest all around us. The baby crowed, and the hired girl's opinion of us seemed to be on the rise as she beamed on us around the corner of the house.

The Rambler forgot he was the principal actor in a swa-ree, when, owing to a defective stand, the hive gave a lurch and slid partly to the ground, grinding up a few bees and making the rest mad; and from a vigorous remark from Mr. McL., as he went over backward on the wheelbarrow, with dog and boy mixed up with him, we judged the swa-ree had just commenced in dead earnest. The Rambler got his head into a grapevine, and secured a position to view the scene. The shouting, running, squalling, and kicking, "beggars description." Let me give you a faint idea with the pencil. The Rambler is now up on the swa-ree question, and is open for engagements.

A SWA-REE.

After the field was clear, things were righ'ed and all unanimously voted, that, next to dynamite bombs, a swarm of bees could get up the liveliest kind of a swa-ree.

I found many things of interest with Mr. McL. He was enthusiastic on button-ball honey. The marshes on the lake, to the extent of thousands of acres, are covered with this bush, and a great amount of honey seems to be secreted. Quantities of basswood are also near by, and bees work here by moonlight when the flow is profuse.

Mr. McL.'s few colonies were wintered in a portion of his barn. A room on the north side, under the evergreens, was sawdust packed, and was a success. The Rambler has noticed that, whenever bees have been wintered in a room on the north side of a building, be it barn or dwelling, they usually winter well. The temperature does not change so much as when the exposure is to the south and to the sun.

Our ramble soon came to an end with Mr. McL. and his family; and as we bade them good-by we (Nig and I) little thought we should see them no more. A few months after, we regretted to learn

that they had all emigrated to Kansas. That so many of our enterprising men and bright families are leaving our midst for the West is many times looked upon with regret by the RAMBLER.

Very good, friend Rambler; but I have a little fault to find with you this time, as usual. Perhaps it is quite clear to the rest of the brethren, but I confess I have not caught on just yet so as to know what "swa-ree" means. If it means a little talk on bee culture, why do the folks call it swa-ree? No wonder our good Catholic friend thought it meant something about swearing. It seems to me that friend McL. is a little heedless about the stands to his hives. I have heard certain folks tell about people who were so awkward that they would fall down while standing still; but I never heard of a bee-hive so badly perched on its stand as to keel over. Why doesn't he have stands made the way I have recommended in my reply to Dr. Miller on the preceding page? Another thing, you did not show us in the picture any of the rocks and terraces that you refer to.

THE VALUE OF EMPTY COMBS

DURING A RUSH OF NECTAR.

I WANT to tell the readers of GLEANINGS that I never realized the use of store combs as fully as last season. It will be long remembered by the bee-keepers of central Iowa as one of the poorest seasons for many years. All through June, July, and the fore part of August, when we usually have our heaviest yield, in vain did the little busy workers search from morning till night for the coveted sweet. It was not to be found. About the 15th of August the bee keepers in these parts began to wear very long faces, and in their "visions and dreams" they were haunted by the thoughts of lean purses and unpaid grocery bills, and more especially by the thought of feeding a large amount of high-priced sugar or see the bees starve. It was about the 15th or 18th of August that I carried my trouble to my good wife—a source from which I very often get relief. Said I, "What in the world am I to do? Here it is the middle of August, and no honey. I am pretty sure we shall have to feed all the bees in the fall to save them through the winter."

Said she, "What *can* you do? I am sure it will not help matters to worry; and, besides, we *may* have some honey weather yet; but if not, we shall have to submit."

Of course, I took this as being excellent advice; but when I walked away I felt pretty sure it was too late in the season for any surplus. Two days later I was walking down the path in the direction of the barn, expecting to assist a neighbor to thrash; but when opposite the apiary I heard a certain roaring sound in the air that the experienced apiarist at once knows to mean a boom on honey. My olfactories in the mean time also took in whiffs of the exquisite aroma of the coveted nectar (of course, that neighbor lost the use of one hand that day). Instantly all hands were engaged in putting on top hives and store combs to all colonies that seemed strong enough to store surplus. In just 24 days there was 1000 pounds put into the store combs,

One very strong colony, that had not swarmed, stored in the 24 days 150 lbs. of surplus, being 114 lbs. more than one other colony nearly as strong that had built their comb and stored their honey in section boxes with starters. So, now, I am more than ever convinced of the value of store combs, especially in a poor season. I had only 36 colonies, as I had made sale of my bees two years before that.

D. E. BRUBAKER.

Maxwell, Story Co., Ia., March 29, 1889.

P. S.—I have taken the 36 colonies out of the cellar, without the loss of one. On the 20th of March they were gathering pollen and honey from soft maple.

D. E. B.

Friend B., had your communication come ten years ago, when we were having hot discussions in regard to the value of surplus empty combs when working for extracted honey, we should have hailed it with cheers, and I do not know but that we might hail it with cheers even yet. Certain parties, and I think that Mr. Doolittle was among them, took pretty strong grounds, to the effect that surplus empty combs were of no particular value. It was at the time when we were claiming great advantages for the extractor, and I believe most of our discussions in the matter have generally closed with a decision something like this: We get perhaps a half more honey by using the extractor; some have said twice as much. Some of the older friends may remember that I insisted that a proper use of the extractor would give two or three times the number of pounds of honey, compared with our best appliances for getting honey in the comb. Now, in the above experiment, although it is not very conclusive, it looks very much as if *four* times as many pounds were secured by the use of empty combs. Of course, the circumstances were peculiar; but if such a thing happens again, what are empty combs worth? Had we better trade them off for five or ten cents apiece, or get still less by melting them up into beeswax, or shall we stick to them, keeping them, of course, nicely protected until the time comes when they will be needed?

UNFINISHED SECTIONS.

WHEN FILLED, EQUAL TO THOSE FROM NEWLY BUILT FOUNDATION.

I MANAGE to get as many unfinished sections each year for use the next year as I can, and not interfere with the present crop. Let us look at a few points. First, the sections: Some advocate cutting out the comb and using the section again. Now, the only objection to the use of unfinished sections is the section itself. The section gets brown, or tanned, and propolis gets in the fiber of the wood, that is difficult to clean out. If I could throw away the wood with convenience, I would do so. I would never save the section for its value. I manage to keep the wood in fair condition, and have never had any one object to them when filled with white honey. Next

THE COMBS.

If they are made nice and white one year, they will be just as nice and white the next. If they have any honey in them, extract it and let the bees

clean them out and they can not be distinguished from new combs when filled with white honey. In fact, it may be whiter than a new comb, for I find that sometimes they will not make quite as white combs as at other times. I have seen them make darker new comb by the side of white old combs. I am very positive that no one can tell old combs from new combs when they are ready for market, by the looks of the combs alone.

THE HONEY.

The honey will be just as well ripened in the old combs as in the new, or else the one who manages is to blame, not the bees. G. M. Doolittle, in *GLEANINGS* for Feb. 1, 1888, has said all that is necessary to say about ripening. Every one of those opposing the use of old combs knows that, in a can of extracted honey, the ripper and heavier honey settles to the bottom, while the greener and lighter rises to the top. The same thing occurs in a cell of honey while ripening. The ripper settles to the bottom side of the cell, and the thinner rises to the top of the cell. If the cell is left as the bees make it, and not turned topsy-turvy, the outer end is the higher, so that the heavier honey goes to the lower and back end; the greener and lighter honey rises to the top and outer end of the cell, so that bees can ripen it just as thoroughly in old as in new combs. Reverse these combs, new or old, and this action of honey is reversed. The thicker will come to the outer and lower end, and the thinner will go to the higher and inner end of the cell. I always keep the same edge of the comb up when I put them back on the hive that was up when they were made. I have no honey capped that is not well ripened, that I have discovered.

THE APPEARANCE OF THE SECTIONS.

The old combs, when filled with honey, and capped over, have a rather better appearance than new combs. The bees will fill the sections out a little fuller, and fasten the combs to the wood a little better with old combs than with new. I have had some experience and good opportunity to test the matter, and there are few things I am more positive of than that section honey is just as good and of just as fine appearance, made on old combs, as on new ones; and I am very positive that no one can tell one from the other, except by the wood of the section. I want to thank G. M. Doolittle for stating the fact on page 79 of *GLEANINGS* for 1888, that the field bees do not place the nectar in the cells themselves, but pass it to the nurse-bees and those that do the housework, because I was laughed at a year ago this last winter, and again this last winter, at a bee-keepers' convention, for making the same statement. Misery likes company, you know.

N. T. PHELPS.

Kingsville, Ohio, March 12, 1888.

Friend P., we are glad to get this report, but I do not gather from it that you have carefully tried both ways; that is, side by side with those mentioned. Have you placed new sections with full sheets of foundation, alongside of unfinished, to see which is filled sooner, and which presents the better appearance for the market? Remember that so good an authority as P. H. Elwood (and I think he said that Capt. Hetherington had so decided with him) says the honey they produce from unfinished sections of the year previous is usually or always sold as second rate.

MANUM IN THE APIARY WITH HIS MEN.

HOW HE DRILLS HIS BOYS TO MANAGE HIS OUT-APIARIES.

APRIL 10.—Well, boys, this is going to be a nice day—just the day to look over the bees for the first time after their long winter confinement. Leslie, you and Fred may go to the Monkton apiary. As Fred is to run that apiary this year, I want him to go there with you; and as you have worked for me six years you need no instructions except to teach Fred all you can and to look well to the stores and queens. I will take Scott to the Mills apiary with me, as he is to run that yard.

Well, Scott, here we are at the Mills yard. How nicely the bees are flying! You may put the horse in that barn there, while I light the smokers. Now, inasmuch as this is your first season with me, I think you had better look on a while and see me work. You will learn much faster in this way than to undertake to work by yourself, as I will try to explain every thing as I go along. The first thing is to remove the cushion. How much nicer it is to use cushions than to have the packing all loose, as I used to have it! There, you see I have the brood-chamber covered with a sheet of heavy cotton cloth, spread directly on the frames, and over this you observe a sheet of enamel cloth which covers half of the brood-chamber. By so doing, the bees can cluster under the enamel cloth whenever they wish to. The other half is simply covered with a cotton cloth and the cushion over all. By this plan the moisture can pass up through the portion not covered with enameled cloth, into and through the cushion. I will now remove this covering and give the bees a puff of smoke to keep them back. This is a fine colony, 8 spaces filled with bees, and all dry and healthy. As they have only 10 combs, we can not remove any yet and leave them honey enough. As we shall probably not come here again within 10 days, it is not safe to contract too much. Out-apiaries can not be managed as closely as the one at home, where we can look to them oftener. There, about all we can do at this time is to see that they have honey in plenty and a good queen, and to see that the bottom-board and entrance are all clear. You will notice that the combs are spread further apart than they should be for summer. I spread them 1½ from center to center in winter; but now we will have them only 1½, and during the honey-flow only 1½. There, now, I follow up with the division-board, return the cotton sheet, and cover the whole top of the brood-chamber with enameled cloth, because, as the bees can now fly nearly every day, they require no upward ventilation, but need all the warmth they can generate during the early spring breeding. Next I return the cushion over all. This swarm, you see, is now compact, and well protected from cold frosty nights.

Well, here is a swarm that is much lighter—only 6 combs covered with bees. From this I can remove two combs—you may carry them to the honey-house for safe keeping. As the bottom-board is covered with dead bees, I open the entrance wide, and with this paddle I scrape the dead bees out through the entrance. Yes, this queen is all right, and laying well. I will close the entrance again, as I do not allow them to have any larger entrance during the spring than I do in winter, which is 2

inches long by ¾ wide, while the summer entrance is 14 inches long by 1¼ wide.

Here is a queenless stock, but it is quite strong. We will remove three combs and clean them out, as we may find a light swarm with a queen that we can unite with these. We shall then have a good swarm out of the two poor ones. One good swarm is worth more than a dozen poor ones.

Here is a light stock with a good queen. We will remove all the unoccupied combs, which takes them all but three. I will now take these three combs and bees and set them in the queenless hive, there I will uncap this card of honey and place it between the two lots of bees. It will serve as a peace-maker. In a short time the queenless bees will discover that a queen is near, and will soon be making friends with her bees, and unite without further trouble to us.

Here we have a hive that the cows turned over when they broke in here. I presume they are all dead. No, there are a few bees—about a teacupful. The queen looks like a young one. Yes, the record says she was hatched last July, and from No. 42, one of my best breeding queens, so I will just cage her, as we may want her in some other yard, or I may have an order for a queen of this kind. There, you see I mark the cage No. 1, as this is the first queen caged, and in my book I say, "Cage 1, queen one year old, daughter of 42." Now, if I should send this queen to any one, or use her myself, I shall know *who* she is. As you see, I keep a record of all my queens, so that I know their age and pedigree.

Here we have another of those strong colonies full of bees and but little honey. Here, I remove two empty combs, and in their place I put in two cards of honey.

This finishes up this yard. You may get the horse while I take a look through the yard to see that we have not left combs out or neglected any thing.

You have now got an idea of what I want done the first time we look the bees over. I shall let you and Fred go to the Eaton yard to-morrow while Leslie goes to Ferrisburgh.

APRIL 20.

Now, boys, we will start out again to-day and see what the bees are doing. There is not much to do to them, but it is best to go around and see to them. One to a yard will be enough this time, as all there is to be done is to see to the stores and give more combs where needed. Should you find any robbing going on, contract the entrance to ¾, and put straw or hay in front of the hive, so the robbers will be obliged to crawl through it. That will discourage them as quick as any thing. Look to those we united, to see if the queens are all right. Should you find any that are queenless, and are strong in bees, give them a card of eggs and larvæ from some strong stock that has a pure queen.

MAY 10.

Well, boys, we have been confined to the shop for some time, and it will do us all good to get out among the bees. Our foundation is all made, and nearly all the sections filled with it. We can finish them rainy days. We shall now spend the most of our time in the apiaries, cleaning up and painting hives, etc.

I will take Will with me to-day, as he has not worked with me this spring. As the old bees have all disappeared, and nothing but young bees are in the hives, it is just the right time to clip the queens

that were not clipped last fall. Here we are, Will, at the Meack yard. These hives being all new, you will not have much painting to do this year, except to give the caps one coat. Now I will let you work while I look on and tell you how to do it. This is a good stock, with seven combs of brood. The record says this is a last year's queen, hence she is one year old. There she is! Now catch her by one wing with your left hand; that's right. Now just let her rest her feet on the lapel of your coat; that will stop her fluttering. Now clip off half of one wing. You see, it is a simple job. Let her go among the bees again. This swarm should have one more comb. Place it outside of the others. Some bee-men would tell you to spread the brood-nest and place it in the center; but I do not approve of it so early in the season. It will do to spread the brood during the honey-flow whenever we have occasion to give a colony empty comb. Next replace the sheets, both cotton and enamel cloth, and tuck down the cushion all around so as to keep them warm, as we now want to induce brood-rearing as much as possible, because the eggs that are laid now, and for the next 20 days, will produce the bees that will gather our surplus; hence we should do all we can to induce the queens to lay in every comb.

Here is a swarm that is not very strong—only four combs with brood in them. You may take out that best card of honey and uncap half the honey on one side, and place that side next to the bees. That is one way of feeding to stimulate brood-rearing; but you see in this case the queen is laying all the eggs the bees can care for, hence the trouble with this swarm is that they are short of bees, so we will go to a very strong colony and take out a few young bees and give to this colony. There, let me show you. This colony is so strong we can take out quite a few bees, and here is a card of nearly all hatching brood, which is also well covered with young bees. I will take it out and hold it in front of the hive—so—and with my knife-handle rap on the frame; that causes the old bees to fly off, leaving only the young bees. Now I place comb and bees in this light stock. Next I will go to that strong stock on the next row, and get a few more young bees on a comb, and this time shake the bees off in the light stock and return the comb. There, now you see I have helped this light stock wonderfully. It will now come up very fast, and perhaps the next time we are here we can give them another comb of brood and what young bees are adhering to it. By this method we shall be able to work up this colony to a good strong one by the time clover blooms, without damaging those from which we take the brood and young bees.

Here is a good colony, but you will find them queenless. How do I know? you ask. Well, I will tell you how I know. You observe the bees are more or less scattered all through the hive. They appear uneasy—restless—and you notice they make a peculiar mournful noise, and fluttering of their wings. Yes, there are queen-cells capped, and not an egg to be found anywhere.

Let's see: The record says she was two years old last summer, hence she would be three years old now. She has probably failed from exhaustion, or perhaps by accident. You may cut out all their queen-cells, and we will give them a card of eggs and larvæ from some of our breeding stocks and let them rear a few cells for us, as we may need

them the next time we are here. Now make a record of this. Let me show you how I do it. There, see:

queen; put in

May 10, 1889. No. 2. Q. P. I. eggs from No. 16. for Q. C. queen-cells.

Here is a colony that seems to be very strong. See how lively they are working, getting both pollen and honey. Yes, just as I expected, the hive is full of bees and brood in 9 combs. These bees are what are called leather-colored. They are almost brown. There is the queen; how dark she is, and how large and lively! Do not clip her, as she is just the kind Mr. Ira Barber likes; and as he has ordered a queen for breeding, I will send her to him next week. By that time it will be time to be thinking about getting queen-cells started, as we shall want a few early queens in this yard; therefore we will leave a record here in the honey-house, which will show that the queen from No. 63 is to be taken out for Mr. Barber, and the one in No. 28 for Mr. J. H. Larrabee.

When you come here next week you will simply have to see to the stores, because they are consuming honey very fast now, and it won't do to let them get short. You will also give those more comb that are not already full. A. E. MANUM.

Bristol, Vt.

To be continued.

Why, friend M., you make me feel as if it would be the nicest kind of fun to be one of your boys. I wonder if you are always as good-natured about it. Suppose some of them should forget and leave a lot of combs exposed, and they have a terrible time of robbing, and some of your best queens are lost. What would you do then? Your idea of having an enameled sheet to cover only half of the brood-chamber, so bees can take their choice, reminds me of my poultry-house, where the roosts at each end run out under an open shed. Just as soon as the weather becomes mild, the fowls walk along on the roosts out into the open shed; but when the nights are frosty and cold, they come into the warm inner apartment. I do like the idea of letting our bees and fowls—ay, and horses and cattle also—please themselves in regard to being outdoors or in. My brother in California went to the trouble of making good dry stables for his horses and cattle. His neighbors laughed at him. Thereupon he left the doors open so the animals could please themselves. As they all stayed outdoors in the rain in that warm climate, rather than go into their comfortable stables, he decided that the neighbors were right—that there was no particular need of stables in that locality.—Your plan of uniting a queenless colony with one weak in bees having a queen, is good. A colony that has been some time queenless will almost always take up with any bees that have a queen. But your comb of honey, with the cappings shaved off, I am pretty sure, from what experience I have had in a similar line, would make a pretty sure thing of pleasant relations among the strangers.—When you spoke about giving a comb of nearly hatching brood to a weak colony, I began to question the wisdom of your course; but when you spoke further about giving them a few more young bees from a *third* colony,

"There," said I, "that fixes it exactly." I often decide a colony to be queenless in just the way you describe, and sometimes I can tell by the actions of the bees around the entrance.—Very likely Ira Barber will be pleased with a dark-colored queen that produces leather-colored bees; but unless you know your man when you send out such a queen, you may get a letter from him that will make things lively. The queen would suit me, however, to a dot.

DEBT AND CREDIT.

OWE NO MAN ANY THING, BUT TO LOVE ONE ANOTHER. ROM. 13:8.

THE matter of doing business cash down, and no credits, has been discussed over and over again; and many large enterprises are conducted, or at least they profess to be, on the basis of cash in advance. The principal argument is, that no one can sell goods at as close margins, and give credit, even limited credit, as they can where they have the cash in hand, before the things leave the store. A good many of our supply-dealers, I believe, have adopted this plan; that is, they do not ship any goods until the cash is first at hand. Now, while this may be every one's privilege, and while it may be true that nobody has any right to find fault if a man decides to do business in this way (so as to give close margins), I do not think, or at least it does not seem to me, as if it were a Christianlike way of doing. One who has a real love and kindly feeling for his neighbors must be accommodating, within the bounds of reason. Selling goods on time, or lending money, if you choose, is a good deal like lending tools. The matter of lending tools has been discussed somewhat in these pages already; and I believe the final decision has been that one must lend his tools—at least to a *certain extent*, to be considered a good neighbor, or, if you choose, a Christian. A man who has built up a beautiful place, and who has succeeded in getting a beautiful farm, with all modern appliances, would, as a rule, be hated, rather than loved, in his own community, if he used every thing he owned, simply for self, and entirely shut down on any sort of accommodation to his neighbors. It is a good deal so in selling goods.

At one time in my life I became so much embarrassed with outstanding accounts that could not be collected, that I decided I would start in business again, and have it all cash down or cash in advance. Two obstacles stood in the way of carrying this out. One was, that it seemed very hard and unfriendly to refuse a little accommodation to those who had for a long time paid cash in advance, and with whom friendly acquaintance had sprung up. Another thing, when there came a boom in business we were oftentimes unable to send the goods as promptly as our customers had sent the cash. We would not trust them 24 hours, but they intrusted us with *their money*, and even then did not get their goods for days and may be *weeks*. Is this fair or Christian-like? Sure-

ly not. At other times, somebody sent money for goods without knowing just what they would cost. Now, if a man sends \$9.00 for something that is worth \$10.00, is it right to hold his \$9.00 and keep him waiting until he sends the other dollar? To be sure, it is not. If, then, it is the duty of a Christian to give credit to a certain extent, who should have credit, and who should not? Here is where the great trouble comes in. To send out goods right and left, to everybody who asks for them, or who makes promises, would be the height of folly. Many of our young friends who have gone into the supply-business have discovered this to their sorrow. In the bee-business, in the small-fruit business, in this whole business of raising crops, it has been well said that it is more work, as a rule, to sell the product and *get the money* than it is to raise the crop. Raising the crop is only one part of the business; and the great trouble is, *whom* shall we trust, and *how* shall we trust? The thought that perhaps I might be able to help some of the friends who are studying on this problem has moved me to write this paper. In our business, looking after accounts, and deciding whom to trust and whom not to trust, has been the most wearing and fatiguing, perhaps, of any one branch of the business. It is this branch of our business that has broken down my health, perhaps, more than any other one thing; and when we finally decided that I must delegate this serious and difficult matter to somebody else, the question came up as to who should undertake it. We finally decided that our oldest and most experienced book-keeper should undertake this, under the advice of Mr. Calvert and myself, when the case seemed a difficult one to decide. As a matter of course, when I let go of the "wheel," if I may use the expression, and intrusted it to somebody else, complaints came in, and it became necessary to frame a set of rules for the guidance of the book-keepers. These rules were those that had been deduced from long experience; and after they were framed they were tested. When we were forced to conclude that we had trusted somebody unwisely, the book-keepers were asked to go back and see *why* this man was deemed worthy of credit; and if our rules were unwisely framed, they were remodelled.

To get the matter before us, let us suppose, as I have done once before, that obtaining credit is like going to your neighbor and borrowing a wheelbarrow. You commence:

"Mr. A, I am a little ashamed to come on such an errand; but just now things are in such a shape that the use of your new Daisy wheelbarrow for half a day would save the price of a good man. Now, if you prefer not to lend it, say so without any hesitation, and I assure you there will be no unkind feelings; or if you can not spare it, that ends the matter."

In the above transaction the neighbor has shown a fair, manly, Christian spirit; and if Mr. A decides he can not spare the wheelbarrow, or decides that he can not lend it

at all, it is his right, and neighbor B should go home pleasantly without it, if his neighbor so decides. It is true, that B might, as he goes off home without the barrow, say to himself:

"Well, I think he showed a mean, stingy spirit. If he does not know *me* well enough to know that I would return his wheelbarrow exactly at the time I promised, and entirely unharmed, he can keep it till it wears out, and I will never ask him for it again."

B *might* say this, but it would be a wrong, unchristianlike spirit if he did say it. Now, let us suppose that it is *money* that B wanted, instead of a wheelbarrow. Ought the case to be materially different? Mr. B agrees to pay for the *use* of the barrow. If he asks for money to be kept for any length of time, he ought also to be just as willing and just as anxious to pay for the use of the money as to pay for the use of the wheelbarrow. You may say that money is not injured by being loaned. We have found to our sorrow, however, that it *is* often "injured." Sometimes it takes quite a part of the principal to get it back again, and a deal of hard, wearing, and fatiguing work. Sometimes it never comes back. How many of you can testify to this? Suppose, now, the wheelbarrow came back all right, but the owner has charged an exorbitant price for it for just half a day. In this case the fault is on both sides. There should have been a plain understanding before the wheelbarrow left its owner, as to what the rent should be. You may say it looks little and small; but, my friends, it does not look nearly so little and small as it does to have a long standing quarrel because there was no understanding at the outset. During my recent travels I felt obliged to decide not to stop at a hotel until I had first asked what the charges were. Some of you may think this looks little and small. I can not help it if it does. After I knew what I was to pay, I could be friendly and neighborly with the landlord, and sometimes with the whole family, without any fear they might take advantage of my good nature.

We now come to another difficult matter. Suppose that B finds it is going to require a *whole* day instead of half a day. Must he go half a mile in order to get permission to keep it half a day longer? By no means. Send the smallest boy over to A's, with a scrap of paper containing something like this:

"Neighbor A, it would be a very great accommodation indeed if I could keep your wheelbarrow half a day longer, and on the same terms. Will it discommode you if I do so?"

If neighbor A scratches at the bottom of the same paper, "Not in the least," it is just as fair as if it were returned at the time promised. The same thing applies to your money. There is nothing out of the way, or injurious to your standing or credit in keeping money longer than the agreed time, providing you get *permission* of your neighbor to keep it. In fact, you may get the time of payment extended seven times, or seventy times seven, for aught I know, providing you make an arrangement that is

agreeable to the neighbor who has loaned it to you. To neglect to do any thing about it, or to write any thing at all, however, when the agreed time comes around, is damaging to your credit, and it must be damaging to any one's conscience. It is not as bad, it is true, to say when the time comes around, "Neighbor A, I have not got the money, and can not get it just now, and you will have to give me more time;" but it seems to me this is not quite the thing after all. The money belongs to your neighbor, just as the wheelbarrow belongs to him, and you have not much more right to keep it without permission than you have to take property without permission. You may not agree with me in regard to this; but if you want your name to be A No. 1, and if you want all business men to spring with alacrity to ship your goods, whether you send the money with your order or not, you must *build up a reputation* for promptness and reliability.* If you want to do this, be sure that some sort of an arrangement is always made whereby payment can be extended, and do this in ample time before the money is due. Most business men are willing, so far as my experience goes, to grant almost any thing, provided they are *notified beforehand*. Another thing that will help you greatly is to be on hand promptly with the *interest*, if you can not pay the *principal*. The record of our ledgers shows that the man who pays his interest promptly will sooner or later pay the principal.† The man who complains in regard to the amount of interest, or who maintains that he should not pay *any* interest, or who *neglects or refuses* to pay interest, usually never pays any thing if he can get out of it. Now, I do not say this because I have a selfish motive in it, but because I think it will be helpful to you all. Broken promises in paying debts are almost as demoralizing as broken promises in signing the pledge. One gets conscience-hardened in a little time, if that is the right term. First, he persuades himself that the interest is altogether more than it ought to be. The next is to decide that he ought not to pay any interest at all; and finally he unblushingly repudiates all obligation, and refuses to pay either interest or principal, and goes along through life *trying* to be happy, and *trying* to quell the remorse of a guilty conscience. To come back to the wheelbarrow again:

Suppose that B should keep the wheelbarrow without saying a word until A could not get along with his work any longer, and went after it. Now, our ledger shows abundance of instances where the result is something like this: First, B says it will cost him the price of the wheelbarrow to have to return it as he promised, therefore he kept right on using it without saying any thing. Again, he says, "I got through with it just as I agreed; but neighbor C wanted it, and he promised to get it around

* "A good name is rather to be chosen than great riches."—PROV. 22:1.

† Our ledgers also show that, as a rule, he who answers promptly every statement in regard to his indebtedness, usually pays all up, sooner or later.

to your place so quickly you would never miss it at all. I am not in the least to blame. The fault is all on C's part." Quite a good many stop right here, and stoutly insist that they are in no way at fault, forgetting, apparently, that the barrow was loaned to *them* and to nobody else, and that they alone are *responsible* for its return or for its value. Again, B will say, "The wheelbarrow was in my barn, and the barn was burned up. Surely you can not blame me for it, for the barn was struck by lightning." Sometimes B adds, "As I lost the whole barn, with all there was in it, you surely can bear the loss of the wheelbarrow." Perhaps A suggests that, as B has had troubles and misfortunes, he will not think of crowding him now, but it seems to him that some time in the future, when B has caught up from the loss of the barn, A thinks he ought to have another wheelbarrow. Now, I have known B to say, a great many times, before they got through, "I wish you had never loaned me the wheelbarrow at all. I never used it a bit, and it did not do me a particle of good."

Well, suppose A should say to himself (I hope he is a gentleman, and will not say it out loud), "I do believe neighbor B is right. It *would* have been better for both of us if I had refused to lend my bright new wheelbarrow; and I declare, it has so often resulted in just about this way, when I have *tried* to accommodate and to do a *friendly* act by loaning tools that it has been no accommodation, and I have just made enemies of my neighbors, I believe I will never lend any more tools." Dear friends, the record of our ledgers has so often shown, in plain black and white, that loaning a man money (or what amounts to the same thing, letting him have goods on time) has only resulted in getting *him* into trouble without doing him a particle of good, that I have been tempted to decide we had better stop it altogether. But a better spirit suggests, "No, my friend, do not stop it altogether, but be more careful in the future." Be careful that the accommodation you feel inclined to grant is not going to bring trouble on both sides.

Before dropping this point I want to say that, of late, quite a few have censured me rather severely for having trusted them. Some of them have been so unkind as to say that it was only a sharp plan of ours to get them into a trap where they could not help themselves. This has come up a good many times when I have urged my right to interest as well as principal. We simply ask for the interest we are obliged to pay—nothing more. When a good many friends find themselves unable to pay at the time they promised, or expected to, I have often written back, "My friend, we are in great need of the money, and really must have it; but to relieve you from your cramped position, as you have stated it to me, I will, if you wish, go to our bank and borrow the money for our own needs, and you may, if you choose, pay me exactly the interest I have to pay at the bank." Now, it is true that a great many—yes, by far the larger part—have written me letters of earnest

thanks for relieving them from the necessity of going out to borrow money, and they have in due time paid interest and principal, saying they would never forget the kindness I had done them. The larger part have done this; but still *quite a good many* have failed to pay me back, even after I have tried to help them, and have talked hard besides.

Now, then, if we are to do a credit business, whom shall we trust? Dear friends, your nearest bank will answer the question for you, and in a plain, common-sense way. Some of you, I know, feel bitter toward our banking institutions, and call them "moneyed aristocrats," and such like things; but, my friends, this is all wrong. If you do not like banks, it is your privilege not to patronize them. But if you do patronize them, and they accommodate you according to business rules, treat them as friends and neighbors. You may say that banks are expensive; but it is your privilege and duty to give up the purchase of things you can not well afford, without reflections on your fellow-men or reflections on the great Father in heaven for giving you only a *humble* station. Do you ask what the conditions are for accommodation at the bank? Well, I presume they will be something like this:

The cashier will say, "My friend, where do you live, and what property do you own?"

If you reply that you own a farm or a house and lot, or a store, the next question is, "What do you consider your property worth, and what incumbrance has it in the way of mortgages, etc.?"

If your property is of a kind likely to burn up, you will be asked if it is insured; and if insured, the summing-up will be, "If you should get sick, or die, or if your house should burn up, or if a cyclone or flood should come upon you, are you in such shape that you would still be able to pay back this money?"

If you are unacquainted with the cashier, he will ask you to call in some mutual acquaintance—somebody to prove your identity, to attest to the truthfulness of your statement—the postmaster, the station agent, or the storekeeper, or people who are known to the banker, and who know almost everybody in the vicinity. Now, if you have had difficulty with any of the above three, or if you owe them money and can't pay it, I shall have to admit that your chances are slim for getting the accommodation you ask. And here we see how important it is that you live according to the spirit of the text at the head of this talk. If you have not done so, you have no right to complain.

Now, suppose you do not own any property at all—you are renting a place. In that case the cashier would be foolish if he gave you credit unless you brought forward somebody known to him—some man of means to sign a note with you to go your security. A great many of you will say right here, "I am not going to ask *anybody* to sign with me." Good! A. I. Root is one of that very sort. But, my friend, if you say you are not going to furnish a signer, you must not

complain if you can not get the accommodation you ask for. You must either get a signer, or accumulate property enough to make it easy for your *wife* to pay your debts if you die suddenly. If you can not do one of the two above things, it seems to me if you are a good Christian you ought not to complain because the world does not see fit to give you credit.

The rules laid down for our book-keeper are just in accordance with the above, only we are a little more liberal than banks in general. This book-keeper, of many years' experience, is a Christian woman of good judgment, and one who has a kindly love for all humanity. In this very work of which I have told you, it is her constant end and aim to decide all these matters in a Christianlike way. Mr. Calvert, her aid and adviser, is also a thorough-working Christian—a man who asks God day by day to help him to love his neighbor as himself. Perhaps they make mistakes. They do not, of course, know all the old friends of GLEANINGS just as I do; but I assure you that we all stand ready to correct any mistake at once, as soon as we are informed of it. I told you we were more liberal than the banks. It is this way: We have quite a few customers who are not men of property—who have very little indeed to fall back on in case of sickness, death, fire, cyclones, floods, etc.; but this class have gained credit by being *prompt* and *careful* about paying all *small* balances. They are often quoted, "Has always paid exactly according to promise," and I tell you this one simple record goes a great way. The man who has always been "faithful in small things," certainly will be faithful in larger ones; but of late a good many facts have come to light, showing that it is *sometimes* a mistake and an unkindness to even these friends to give them *too large* a credit. Very often I pencil on letters, "Why was this man trusted?" The letter comes back to my special box, marked something like this: "He was always prompt, and fully up to promise in small amounts, say from five cents up to five dollars, until we decided to trust him \$25.00, then he had bad luck, and wrote us once or twice about his misfortunes, and now we can't get any answer from him at all." Now, friends, the fault was ours. To be kind and helpful to this individual, our duty was to tell him that we did not feel justified in trusting him to so large an amount as \$25.00, from what we could learn of him, even though his past record had been excellent. Very likely he would have been greatly hurt and pained on receiving this answer; but it would have been much better for all parties, just as it was with the wheelbarrow, had neighbor A stated kindly but firmly that he preferred not to lend it; and, my friend, if you know the neighbor who comes to borrow your wheelbarrow is notorious for breaking and injuring and keeping every tool he gets hold of, I think the kindest act you can do is to tell him pleasantly, that, if he will excuse you, you would rather not lend it.

Some years ago I wanted accommodation at our bank. The cashier questioned me,

and finally told me he did not see how they could consistently let me have what I wanted, especially as I objected to giving a signer. I urged, however, and he finally said that perhaps they could get around their rules in some way. After a little reflection I decided, however, and spoke out something as follows:

"Look, here, my friend, I do not want to be any exception to your regular rules. I want just as good terms as you offer to anybody else, but no better. If your rules are as you have stated, I prefer to abide by them;" and I went without the money I wanted, and felt then a good deal happier, and have ever since. And you too, my friend, will feel better and happier and *manlier* to abide by the established rules than to beg to be an exception because you are a "near neighbor," or an "old friend," or something of that sort. I am sure a little foolish pride often comes in here. Men who are worth their thousands do not feel hurt, nor object to being questioned; and I believe it is generally laid down that the man who flares up and gets offended, or shows anger because he is asked to submit to the regular established business customs in the way of debt and credit, is, as a rule, found to be unworthy of *any* credit.

Some years ago a good friend of mine, who is in the banking business, wrote me a kind letter. After excusing himself for taking the liberty, he said he would like to urge upon me the importance of keeping a little more ready cash ahead, so that I might not be so often in cramped places. He said it injured my standing, not only as a man of *business*, but also my reputation as a *Christian*, to have the world see that I was cramped or pinched, or to be inquiring here and there for money. Now, this friend is not a Christian; but from a business standpoint he saw that I was dishonoring Christ Jesus the Savior by continually paying out my money as fast as I got it, or a *little faster*, so that I was every little while crowded. I thanked him, and told him that I would try to show him that his advice was not thrown away. In a little time I had quite a sum of money in the bank, saved up for a "rainy day," as the expression goes; and during that summer I was enabled to take advantage of many opportunities in the way of purchases, that I had never been able to manage before; and I resolved then that I would never more dishonor the Master by want of ordinary business prudence; and let me tell you, my friends, that, although we like to do business, and like to sell you goods, I would urge and implore you, not only for your *own* good and happiness, but for the sake of *Christ Jesus*, not to be in such haste to make such investments that you *cramp* and cripple *yourself*. Read over again the little clause in the fore part of our price list, about borrowing money to buy goods.

A few have objected to 8 per cent interest. Some have said they did not think we were *obliged* to pay it; and a few have said that we are not very smart in business or we would *not* pay 8 per cent interest. My friends, we can get money at 6 per cent by

keeping it a year or more, and by furnishing a signer. As we do not get it at that rate at present otherwise, I prefer to pay the 8 per cent, especially because, by so doing, I can better fulfill the command of the little text I started out with—"Owe no man any thing, but to love one another."

GREAT RHINOCEROS BEETLE.

NOT AN ENEMY, AFTER ALL.

I HAVE the following letter from E. Wetherold, Bryantown, Md.:

Respected Friend:—I send you a beetle which is a curiosity to me, as I have never seen one like it before. I wish you would describe, illustrate, and give a sketch of its mode of life and habits for the readers of GLEANINGS. I am sure it would interest all. It was found in a decayed locust-tree which has been gradually dying for some years. Are these insects the cause of the death and decay of the trees? Locusts in this State are seriously injured by what are called borers. I have never seen these borers, but supposed them to be quite different from this beetle.

GREAT RHINOCEROS BEETLE, NATURAL SIZE.

This beetle (see cut) is one of our most formidable-looking insects. It is known as the great rhinoceros beetle (*Dinastes titys*, Linn.). Its form, size, and markings are well shown in the excellent figure which I inclose. It is greenish in color, often with a yellowish tinge, with black dots. The ends of the horns and the legs are black. It is reported that some of them are uniformly brown, like our May beetles. The lower horn can be moved so that, as it comes against the upper, it might form quite a formidable weapon of offense and defense. On each side of the pro-thorax is a short horn, one of which shows in the figure. Indeed, though perfectly harmless it is about as startling in its appearance as any insect I know of. It is a Southern species, and has been found from Maryland to Missouri, in southern Indiana, and to the Gulf. The grubs feed on decaying wood, and so this one does not destroy the Maryland locusts. The beautiful locust-borer, a trim, long-horned beetle, yellow and black in color, is the real enemy, and it is a serious one all over the United States. When the trees decay from the attack of the locust-borers, then this rhinoceros beetle finds in it a suitable nidus for its eggs. Thus it is not strange that our friend Mr. Wetherold found this one as he did. The female looks like the male, but has only a tubercle in place of the long horn. I should be very grateful if some Southern friend would send me a female. I am very glad to receive all such insects, and will gladly describe them when sent to me.

A. J. Cook.

Agricultural College, Mich.

THE SIZE OF BROOD-CHAMBER.

DADANT STRONGLY IN FAVOR OF LARGE-SIZED FRAMES.

IN the answers on the number of brood-frames in the hives, page 224, we give the larger number, while Messrs. Doolittle, Hasty, and, I could add, Gravenhorst, as per his article, page 210, use the smallest-sized hives. Let me tell how I came to the conclusion that large frames and capacious hives give better results than small ones. When I arrived in this country, 26 years ago, I had never seen shallow hives; so my first hives were made of the same size as the Debeauvoys, $12\frac{1}{2} \times 14$, which was about the same as the American, 9 frames to the hive. A little later I tried the Quinby hanging frame; then enlarged both kinds, to place at the sides glassed surplus boxes, as per the idea of Mr. Jasper Hazen. But seeing that bees were reluctant to work in the side boxes I replaced them with frames. My American was thus enlarged to 14 frames, and my Quinby to 13. But as my best queens had too much room in these Quinby frames, I reduced them to nine or ten, with one or two partition-boards besides. Yet as I had begun to raise bees for sale, and as most of my customers wanted them in Langstroth ten-frame hives, I had to comply with their preferences, and introduced this size in my apiaries, being thus enabled to experiment on three different kinds of hives. I had begun, also, to raise Italian queens for sale, using at first small nuclei with combs 5×5 inches. But as I had to cut my combs to give brood or honey to these nuclei, I got the idea of dividing a few of my large Quinby frames in two equal parts, which could be taken apart or reunited at once. A small engraving of this device appeared in GLEANINGS for March, 1874, page 28. I made 25 such nuclei, every one of 11 half Quinby frames capacity. I used these nuclei with the best results as long as I raised queens for sale. It was an easy matter to keep them strong and well provisioned by borrowing from those of my hives in which I had introduced some of these divisible frames.

In the latter part of summer, as fast as one of these nuclei was deprived of its queen, its bees were given to another, and so on till the eight or ten left had a sufficient number of bees for a good wintering. Yet, while these small hives wintered perfectly, I have been unable to build them up in spring to the strength of my large hives; for at the beginning of June, while my Quinby had, on an average, seven or eight combs full of brood, my nuclei had hardly brood on eight or nine half-combs.

Having narrated these facts lately in the *Revue Internationale*, of February, 1889, its editor, Mr. Bertrand, added in note:

"It is a similar observation, made about ten years ago, which has definitively convinced us of the superiority of the large frames. Supposing that the keeper of one of our apiaries desired to have bees of his own, we gave him a swarm and a few hives, known under the name of Vaudoises, and containing 13 frames 11×10 inches. This apiary of our bee-keeper, placed on our own ground, side by side with our own bees, increased in number with time, but these small Vaudoises have never equaled, neither in population nor in product, our large layers" (14 to 16 frames, of the American size).

There is in the A B C a very good explanation, with engravings, of the causes why bees raise less brood in the Gallup than in the Langstroth combs, so we can easily understand why Messrs. Doolittle and Gravenhorst think that a good queen can not lay more than 2200 eggs daily, while I have often noticed some laying over 4000 eggs for weeks.

The opinion of Berlepsch on this matter, as given by Mr. Gravenhorst, is of very small account, for the frames of the Berlepsch hive are of about the same size as those of Mr. Gravenhorst. I may add, that a great many comparisons have been made in Europe between the 11-Quinby-frame hives and the Berlepsch, and the results were always wonderfully in favor of the large Quinby; in fact, they showed from two to three times as much honey per colony in the Quinby, in the same apiaries. No doubt Mr. W. P. Root, your translator, has noticed these reports in the *Revue Internationale* of Switzerland, and in the *Apicoltore* of Milan, Italy. The journal of the Marches, Italy, *I Api e i Fiori* (The Bees and the Flowers), was founded in view of spreading the wide hive under the name of *arnia marchigiana*. But some bee-keepers, in this country, object to large hives for comb honey. My first comparisons were begun about 23 years ago. At that time I used slatted honey-boards, on which my glassed honey-boxes were placed; but after noticing that bees were slow to ascend in the boxes, I dispensed with honey-boards by inventing T supports made of plasterers' laths, under the edge of which I nailed tin strips above, 2 inches wide, to support my boxes directly above the brood-frames.

When — twenty years ago — Adair invented his sectional honey-box he sent me one for a pattern, and I discarded the square glassed boxes. I had an extractor; but as the people were reluctant to buy extracted honey I produced more especially comb honey till a part of the prejudice was overcome. The size of my hives was far from being a hindrance, for I took sometimes 150 lbs. of spring comb honey from my best colonies, although our spring crop is gathered on the white clover exclusively, since we have very few lindens around here.

As our queens have room to lay from 60,000 to 80,000 eggs in 21 days, the population is so large that we do not need to contract the brood-chamber, the workers being too happy to find their room enlarged. We have had swarms containing 60,000 bees or more, if we estimate them by their weight, while Mr. Gravenhorst speaks of uniting two of his swarms to get 44,000 bees.

Our experiments are still continuing on the three kinds—11-frame Quinby, 10-frame Langstroth, and 14-frame American; not on two or three of each kind, but on 50 or more. When we extract we begin with one kind; and when it is done we figure the result, dividing it by the number of colonies. We do the same for the other kind, placed side by side in the same apiary. Then when we say that our large Quinby gives us better results we know there is no mistake. To sum up the above we will say that, according to our quarter-century's experience—

1. In a large hive the queen, in spring, begins to lay earlier, and lays more than in a small one, since the population wintered is larger.

2. At the beginning of the spring crop, the number of bees is so large that, as soon as the surplus

boxes are placed, the bees ascend into them without needing contraction.

3. As the queen finds sufficient room to lay, she goes upstairs so seldom that we dispense with queen-excluders.

4. If the boxes are furnished with combs and comb foundation, and more room is added before being needed, all swarming will be prevented, except when the bees replace their queens during the honey crop. As we do not get more than two or three per cent of swarms, we dispense with watching our bees closely.

5. As bees swarm but little in well conducted large hives, not only the time and work of the bee-keeper are spared, but the day of swarming is more profitably used by bees in going to the fields and getting, according to circumstances, from 5 to 20 lbs. more honey per colony.

6. The few swarms obtained are so large that they need hives of full capacity, and one or two surplus boxes, in which we sometimes harvested 100 lbs. of honey or more.

7. As all the queens have a sufficient space to lay to their utmost capacity, it is an easy matter to breed from the most prolific, prolificness being the first qualification of a good queen.

8. As we leave about all the honey stored in the brood-chamber, our bees have some spring honey left for winter; and as this honey is of the best quality they winter better on it, while we dispense with the work of feeding.

9. As the laying of our queen is never restricted, her large population has the best chances to reach spring strong and healthy.

We desire to add, that none of the bee-keepers who oppose large hives have ever tried them, and act under the influence of preconceived ideas; while we speak with the authority that a long experience can give, and are backed by hundreds of European and American bee-keepers who have made the same comparisons that we did.

Hamilton, Ill., April, 1889.

CHAS. DADANT.

There, friends, we have a valuable article. Now, although it should not seem prudent for us all to adopt the large Quinby frame, I do think it behooves us to think well before we choose a smaller frame than the old standard Langstroth. I have for years been well satisfied that we could raise more bees with a frame larger than Langstroth's, for the reasons that Dadant has given; but when other things are taken into consideration, especially the matter of securing comb honey, and getting sections close to the heart of the brood-nest, I think I would use a frame a little shallower than would otherwise be needed; and then when we reflect that most of us have the Langstroth frame already, it seems to me very good policy to let well enough alone. By the way, one can not well avoid the conclusion that friend Dadant has some extra-prolific queens, especially those that lay 4000 eggs in 24 hours, and keep it up for weeks. I do not know where he gets his stock to raise queens from at present; but I am inclined to think that it was imported from Italy, not very long ago. Will he please tell us about it? I presume that it will, of course, be of no use to have such large hives unless we also have queens to match.

MOVING BEES DURING THE SWARMING SEASON.

ALSO SOMETHING ABOUT SETTING BEES ON DIFFERENT STANDS WHEN TAKEN FROM THE CELLAR.

On page 165 friend Daniels speaks about moving bees in and out of cellars like so many potato barrels "and not one word about losing bees in all the years I have been reading bee-papers." Why, friend D., unless I'm very much mistaken there has been a good deal said about it, and I think that the majority of bee-keepers insist that, when taken out of the cellar, each hive must be put on the stand it occupied before going into the cellar. Certainly I have no recollection of any case where bees were taken out for a fly, put back in the cellar again, and then, when taken out next time, no care taken to put them on the same stands.

In all cases it is entirely safe to put a colony back on its own stand. Sometimes, however, it is not convenient. Take my own case. In my cellars are now bees from four apiaries. Without much trouble I could put all that belong in the home apiary on their own stands. Even then if I had nothing but these, and if a goodly number should die in wintering, I believe I should rather have the survivors fill out the rows solid as far as they might go, rather than have vacancies. But those colonies which come from the out-apiaries can not be put back where they stood last fall without a great deal of trouble. You see, it is not easy to have regular places for them for the few days in fall and spring that they stand near the cellar. But after those bees have been in the cellar about five months they don't seem to pay any attention to their old location. I set them where it happens to suit best, without paying any regard to their previous location.

Before going any further I want to advise you, if you are a beginner, to set it down as a rule, that, if you don't want to lose bees, you must be careful not to change their location. You haven't a great many colonies as yet, and you can easily place them in spring where they stood the previous fall. Experiment somewhat gingerly to see what *your* bees will do with *your* management before you risk putting many on stands new to them.

Now I may go on to say that, in my own case, even if they do mix up some I don't know that it is any loss, although I should rather have each bee stay in its own hive. If I should move bees as does friend France (see page 81) I should rather expect trouble; still, I can readily believe that he gets along all right with it. But as to having a cluster cling to the old stand when put on a new stand in spring, *I never had a single case*. I can imagine that, if I had very few colonies, or only a single colony, and should give it a stand in the spring, a few rods from the old place, a large number of the bees *might* gather at the old stand and keep up such a commotion there as not to hear the hum of the bees at the hive, and so cling to the old stand. But if a large number of colonies were in easy hearing I have little fear but that the old stand would be speedily deserted, and the bees would go into hives most likely not their own; for on first being taken from the cellar, bees of different colonies seem to mix peaceably. Another thing: If, during the rush of the honey-flow, a colony with no others near it should be moved half a mile, or, indeed, any

distance within the scope of its previous flight, I should expect to see a cluster at the old stand. From the headlong way in which a bee rushes from the hive in a bee-line after a load of honey, one can easily believe that it pays little attention to its surroundings till it is some distance away. Now, suppose this bee should be taken to a new location two miles away. On going out to-morrow morning it strikes within a few rods upon a linden-tree upon which it had been at work the previous day. Even if this tree is two miles from its old home, it knows well the way back, and it doesn't know the way to its new location. Is it not the most natural thing for it to fly straight back to its old home? By the way, is not this some proof that bees in general do not fly so very far, for I think it is generally understood that bees moved in the harvest two miles from home, will never return? If that distance was within the range of their previous flight, would they not return?

Now, upon coming back to the old stand I should expect to see a large cluster remain there. But if another colony were within a very few feet, or a number of colonies within a very few rods, I should hardly expect to see a single bee remain for any length of time on the old stand. I have often removed a colony from its stand in the middle of the harvest, and I don't believe a colony thus moved ever lost a dozen bees, or, rather, that a dozen of such bees were ever *entirely* lost, for the whole field force will fail to find the hive when thus moved; but they will peaceably unite, when loaded with honey, with one of the nearest colonies.

On page 81 you say, friend Root, "When they are moved so far that they do not meet familiar objects on their first flight, of course they will all go back to the hive." Now, I am a little skeptical about that, unless some modifying words are used. How far will a bee in a strange place dart from its hive before it recognizes that there are no familiar objects? I wish that some one who can, would answer that question. I hardly think it awakens fully to the situation till it is at least a number of feet from the hive. When it does think about it, it doesn't know where to go; and if other hives are standing near, will it not be just as likely to go to one of them? There is likely to be an unusual commotion at the hive which has been moved, and this will probably prevent many from going wrong, but I have for a long time had some suspicion that when I moved bees to an out-apiary, there was more or less mixing up. C. C. MILLER.

Marengo, Ill.

Friend M., I am well aware that bees do mix up a great deal from one hive to the other; and especially is this the case when they are first taken from the cellar. We can tell exactly how much they mix by having a part of our apiary Italians and the other part pure blacks. We shall then find black bees scattered among the Italians, and Italians scattered among the blacks. In regard to your point about moving, so that they do not meet familiar objects, the first colony of bees I ever owned was very carefully watched. I was down before the hive in the morning before a bee had gone out, and I have repeatedly watched bees from colonies that had been brought in the night before; that is, I would sit down by the hive and see how the inmates behaved when they

first discovered they were in a strange neighborhood. So far as I can recollect, they always took their points. I do not remember to have seen a bee under such circumstances go right off to the fields without noticing that the surroundings were different, and I have always supposed that the minute they discover they are in a strange neighborhood they take their bearings as bees do from a newly hived swarm. In purchasing bees from our neighbor Rice, about 10 miles away, I often watch them when the wire cloth is taken from the entrance. Under such circumstances they come out with a rush—a great lot of them, while others stand humming at the entrance, and, as a general thing, I think almost every bee very soon, and without going a great distance, goes back to the hive he came from. Pretty soon they sally out for another reconnaissance, and within a couple of hours some of them will return with pollen. Now, if neighbor Rice lived within half a mile I should expect these pollen-gatherers to go to their old home with their loads; but so far as I can recollect, where they are moved a mile there is not often much going back; a mile and a half, almost none of it; and when you come to two miles, I never saw a bee go back at all. When I brought the first Italians into Medina County I watched this matter very thoroughly. I do not believe that *our bees often fly more than two miles*. In the last issue, p. 308, J. F. Whitmore had something to say on the same subject.

FROM SAN DIEGO TO DEHESA.

A RIDE THROUGH THE COUNTRY.

FRIEND ROOT:—At 6 o'clock to-morrow morning you will take a seat in my buggy, behind my messenger horse John. We will journey to the east, for Dehesa is 25 miles away, among the mountains, 1200 ft. above sea-level. Now, I am to do most of the talking; first, because I am older; second, because I know more of the country than you do. There, we have left the city behind; and at a glance over our shoulder we can see a thousand little clouds of smoke, rising from so many chimneys, where the busy wives are preparing breakfast. Look just over those little clouds of smoke, and you see San Diego Bay. How peaceful and smooth it is! and when you open your eye a little wider you see Coronado, with its grand and imposing hotel (the largest in the world).

But here we are, three miles out of town, and what have we? Only a gravelly soil; low, gently sloping hills, covered with brush. Why is this land in this state of nature? Is it not good for any thing? Yes, nature has bestowed upon this soil all that is necessary to raise good grain, fruit, berries, vegetables, nuts, and flowers; in fact, every thing that goes to make a prosperous and happy home. Only one thing is lacking—*water*. Water is king in this country. But, wait! You shall see, as we go further on, the source whence all this land shall drink, whence all the dense population that shall build for themselves homes upon this self-same soil in this delightful climate, where old Jack Frost seldom if ever comes, and then only to nip the

tenderest flower or shrub. Go on, John; let's jog along and show Mr. Root, at "five miles away."

Here we are. This is not a bad-looking place on our right; fine house, fine barn, fine out-buildings, and it looks nestled snug in that little canyon; the henry—*that* looks a good deal like home, does it not? Look to the left, and you see the orange-orchard. Yes, the trees are small. You were not with me one short year ago when John and I traveled along here, much as we are doing now. Well, then there was not a blow struck, the brush was waving in the morning breeze, the jack rabbit sported on hillside and valley. You ask, "How comes this transformation in one short year?" I tell you, money and Water (put the capital for Water, for 'tis king). This man was more fortunate, perhaps, than all would be, for he struck a big flow at a reasonable depth; and with his 14-foot windmill he hoists it to his tank, thence to the thirsty earth about his ground and trees. But we must hurry on.

Now you see the small house on the left; that is the six-mile house, where Mr. Harbison used to have his first out-apiary, now sold out and gone, for the bees must go further back. You see but little change in the face of the country. The same undulating hills and valleys, the same sandy soil, and brush and jack rabbits, but no houses; no, none. Two miles more, and here is the eight-mile house where the greatest stock in trade is bad whisky. Let's hurry-up, John, and get out of this locality, for we are coming into America. Every turn of the wheels brings us into a higher altitude; and now if you will put on your glasses, over that joint at the left you will see an oasis in this wilderness of brush and low hills and gravelly soil. Here is home again, with its comforts and two wind-mills. We are now 700 feet above San Diego Bay, and within a stone's throw of the first crossing of the Cuyamaca & Eastern R. R. This word "Cuyamaca" would be spelled and pronounced in English (Quemahka). This road, that is now building as fast as men and money can push it through, will be one more through line from the great East to the western shore; and the next time you visit San Diego you will be hurried along at 40 miles an hour over the very ground over which we now sit.

We have left the sage brush behind for a time, and this newly turned-up soil on our right tells of culture, thrift, progress, and the go-ahead spirit of the true *American*. Do you see that streak of newly turned-up soil? Look at its meandering course, over hill and valley, now to the right, now to the left, but still on and on to the sea. That is the path where lies hidden the great water-pipe from the San Diego flume (but you shall hear more of that when we get to it). The summit! here we are, 11 miles from the city, and 900 feet up. You see no more brush, but cultivated fields; and if you will hold your breath for a little while, John will let us down to the first crossing of the great flume and the second of the Cuyamaca. Here they are together. While we contemplate the beauty of this body of fresh mountain water, flowing so peacefully beneath us, we can not but admire the skill and energy of man that has hollowed out and cut this path through the mountain-side for the locomotive, for the wagon-road passes over them both at this point. But on a few rods, and we will put on the brake, while you feast your eyes upon the scene below. This is the El Cajon Valley. "Cajon" in

English would be spelled *Cahone*. Now what do you see? You have come 14 miles to this lovely valley. Spread out before you are thousands upon thousands of acres of fruit and vines—a real paradise—nothing fanciful about it, but real. Here you find a soil rich, deep, and productive—no hillsides here, no grade, no brush, nor jack rabbits. Beautiful, is it not? Does man live here? Yes, 'tis the hand of man that has turned this into real beauty. Get-up, John! Past all this semi-tropical beauty we will wend our way to the Southeast Pass, and toward more beauty, or old Sweetwater, now Dehesa. Do you look over my shoulder to the right, at that fine house and grounds, with its young orange-orchard, vineyard, and 200 acres of barley? Last March, when I rode along here as we are doing now, the house was not yet done; men were busy setting out trees and vines; four plows were turning up the virgin soil for the first time, all in 12 months. But, halt! here we are, beneath this great flume; 82 ft. above our heads flows 5000 miners' inches of water. This trestle, that extends on either side of us, is 1232 ft. long; and what a splendid structure it is, so solid, so strong! Now let's stop a moment and think what a stupendous work is this, and what does it mean to San Diego City and County. Fifty-five miles away, where the peaks of the Cuyamacaes penetrate the clouds, there is where this water comes from. This enterprise cost over \$1,000,000, and this now is what I promised to tell you several hours ago, when we were passing over the thirsty land this side of the city. This is what is going to give that land to drink, to make it bud and blossom, and to make plenty and contented homes all over that now barren waste. On and on, for time presses, 1000 feet now above the sea, and here is Mr. Rose—not a bad house has he got either; and just done. Do you see those ricks of baled hay, the orchard, and vineyard, where 18 months ago not a blow was struck, and Uncle Sam was owner of the land? 'tis true, every word of it. Brace yourself, for John is letting us down the McFarland grade. Whoh there, now! let your eyes do their best. The eye can take it in, but the tongue can not express the scene below. It is the Sweetwater Valley. Look! in yonder distance you see the sweet water coming. It will not pass us. Turning to the right it passes on and down to the great Sweetwater Dam. Before you now is the valley, the land where the celebrated Dehesa raisin of California is raised. This, now, on the right, is Mr. Allen's and Mr. Weddle's, all in one field, you say. Yes, 400 acres in one vineyard, besides fruit. We must certainly hurry on; and while we pass farm after farm with their surroundings, think what will this country we have come over to-day be and look like ten years from now. Let the mind picture the condition then. Here we are at the mouth of Harbison Canyon; one mile up grade, and we are home.

A. W. OSBURN.

Dehesa, San Diego Co., Cal., Mar. 14, 1889.

Well, old friend, you have given the readers of GLEANINGS one of the best pictures of California that I have ever seen—that is, the best pen-picture. It gave me a feeling of pain all through, however, to think that I bungled my trip in such a way that I did not make the trip with *you* in reality. I saw a great deal of what you mention; and I kept saying again and again to myself, "What is to be the outcome of these won-

derful improvements in the next ten years—yes, or even five years?" My brother Jesse and I visited El Cajon, and went through one of the large raisin plantations. That wonderful flume and those gigantic trestles were to me an unceasing wonder. In fact, I did not know, until I viewed that trestle-work and the Sweetwater Dam, that the combined skill of the mechanics of the world could produce any thing so imposing and grand in the shape of mechanical architecture. The work is not only a miracle of strength, but it is to me a miracle of beauty; and the very idea of pouring pure bright limpid water into those desert wastes, and making the wilderness blossom as the rose, fills me and thrills me with enthusiasm. Now, if I had had that buggy-ride with you, before we had been together many hours I should probably have given you an exhortation, after my fashion, in the way of praising God, "from whom all blessings flow." May be you have done that thousands of times, and are doing it every day of your life. If you have not, then why shouldn't you commence now? The very sight of those mountains, especially with the railroads, the great flumes, and dams, contrasting and comparing man's work with God's, seems to me should make any human being feel that God's plans *include* man's, and that his design was in the very outset that there should be mutual love and harmony between God and man. God loves us, or he would not have taken all this pains; and it seems to me that the highest and holiest and noblest thing that man can do is to love God and look to him in thanksgiving and praise very often; and especially when beset by troubles, doubts, and uncertainties does it behoove him to "cling to the rock that is higher than I."

HUBER HIVES.

FOUL BROOD, ETC.

MR. WM. C. BROWN, Otago, New Zealand, sends me a frame by sample post which he describes. He wishes me to give my opinion of it in GLEANINGS. This is really a Huber frame, like the Quinby, Bingham, and new Heddon, only this is closed above and on the sides. The idea is, that there should be no space between the comb and side of the hive, nor any upward ventilation. Very likely a valuable end is gained in the use of such frames. We should judge so from the fact that they are used by such persons as Captain Hetherington, Bingham, etc. The only question is, Does the advantage gained cost too much? To close all openings above would necessitate exclusive side-storing. I do not believe such a system advisable. No one uses it in America, so far as I know. Indeed, I do not believe it very important. The bees seal the top of the hive very closely, and I can see no objection to a shallow space—bee-space—above the frames. In fact, I like it. I have used several hives of the Huber type—closed-end bars—and I believe, after all, that, for the general bee-keeper, the regular Langstroth hive is yet the best. The convenience is more than the slight advantage gained by omitting the end space between the

frame and hive. Indeed, I am not sure that, even in wintering, the old box hive is superior to the Langstroth, especially in wise hands.

Mr. Brown asks me if I think it wise to legislate on foul brood. He asks if the same money and effort put into research will not accomplish more. In reply, I will say that a somewhat similar malady attacks the peach-trees in Michigan. A law was passed requiring the immediate removal of diseased trees as soon as the malady was discovered. That law has saved thousands of dollars to Michigan peach-growers. It was enforced till people saw its value. Now no law is needed. Why would not or might not the same be true in case of foul brood? We have a law in Michigan, but have never had to use it more than once or twice, I think. The very fact of the law seems to have brought the required action without any legal proceedings. We understand the disease pretty well now. One of Michigan's best bee-keepers has had it for two or three years. He told me last summer that he did not fear it at all. He rather enjoyed dealing with it. This man, however, has a big brain, and he knows how to use it.

A. J. Cook.

Agricultural College, Mich.

Friend Cook, this matter of closed-end and closed-top frames, made in such a way as to give them the advantage of the old box hives, has been discussed for more than twenty years through our bee-journals, and I believe the general decision has been in accordance with the views you give. I think you are sound, also, on the matter of legislation in regard to such things as foul brood, the malady that threatens to ruin the peach-trees, and other like matters. It is not because people deliberately propose to harm their neighbors, but it is the ever-prevalent sin of neglect and procrastination. In California, by efficient measures in Ventura County, foul brood has been practically extinguished; but they were obliged to elect some one as inspector, and have him visit the apiaries, and decide what ought to be done. In no case that I heard of did any one dispute the justice of the law, or refuse to do as the inspector directed. But without the law, and the inspector to visit apiaries, make examinations, and decide or advise, if you choose to put it so, what is best to be done, nothing would be accomplished. The simple matter of letting people know that such a law has been passed, is often all that is needed to stir them up to a sense of duty.

O. O. POPPLETON.

A SKETCH OF HIS LIFE, BY HIS SISTER-IN-LAW.

O. O. POPPLETON was born near Green Springs, Seneca Co., Ohio, June 8, 1843. When four years of age his parents removed to Napoleon, Henry Co., Ohio, where, two years later, his father died, leaving his mother a widow with two sons, in straitened circumstances. Two years later his mother married Mr. Joseph George, of Clyde, O., and settled in Sandusky Co. After living there a few years the great inducements of the West influenced his step-father to move to Northern Iowa, where they settled in Chickasaw Co., when Mr. Poppleton was 12 years of

age. This was his home until two years ago, when he removed to Florida on account of his health.

As Iowa was a very new country, Mr. Poppleton had the full benefit of pioneer backwoods life. His education was obtained in common schools, except about two years at Oberlin, where he also took a commercial course. When 16 and 17 years of age, in company with an uncle of his he taught writing-school at several places in Ohio—at Lithopolis, Homer, Washington C. H., and Springfield; at the latter place he also kept books for a short time in a daily-paper office.

O. O. POPPLETON.

In October, 1861, he enlisted as a private in the 7th Iowa Infantry, and re-enlisted as a veteran in 1863. In February, 1864, he was promoted to a lieutenantcy in the 111th U. S. C. Inf., and a few months later he was made regimental adjutant. It was while performing the duties of this office, and also at the same time those of post adjutant at Murfreesboro, Tenn., that overwork resulted in the eye trouble that has so seriously affected his health ever since, and which compelled the refusal of an excellent offer of employment at the time of mustering out. He served his country faithfully for five years; and though he received no scar upon his body, yet the smell of smoke was strong upon his garments. He was in several hard-fought battles, and taken prisoner once, but was held only a few weeks, when he was released or exchanged.

On leaving the service he settled down on a farm adjoining his parents' in Iowa. He married a Miss Groom, who died twelve years after, leaving him two daughters. Mrs. Poppleton was a confirmed invalid for nine years.

Dec. 6, 1881, he married Mrs. Mattie Herrick, of Ft. Wayne, Ind., who is a sister of the writer of this sketch. On account of poor health, and the very severe winters of Iowa, they went to Florida to spend the winter for several winters, where he found the change of climate, with outdoor living, greatly improved his health.

Mr. Poppleton is a great sportsman, and takes much pleasure in hunting and fishing; and as the climate in Florida is just suited to that kind of work, he enjoys living there, exceedingly. As his wife also has poor health, they spend much time camping out, which way of living seems to agree with them, and they feel much stronger and better than when living indoors. On their return home from the South they brought a great many curiosities, some specimens of the beautiful Southern birds, such as we do not see in the North.

When first married, his step-father gave him a colony of bees in a box hive. It so happened that, in the winter of 1869, an acquaintance stopped over night at his house, and among other papers he had with him was the bee-paper that was at that time published by H. A. King, at Nevada, Ohio, now the *Bee-Keepers' Magazine*. This he became very much interested in during the evening, and immediately afterward obtained all literature on bees he could find, and made a study of the "busy bee." He soon learned there was a better way of handling than in a box hive. He transferred the two colonies he then had into movable-comb hives; obtained other colonies, and in a year or so had quite an apiary, which, in common with so many other apiaries in the country, was almost destroyed by bad wintering. But the use of chaff hives removed this trouble for the future.

On account of having such poor health he made no effort to do a large business, but confined himself to a simple apiary varying from 75 to 150 colonies, spring count, and to the almost exclusive production of extracted honey. For the last ten years that he lived in Iowa, his annual crop of honey averaged 110 lbs. per colony. His half-brother, F. W. George, has had charge of his apiary since his removal to Florida.

Some fourteen or fifteen years ago he discovered the value of chaff as winter protection for bees, without knowing that any one else, notably Mr. J. H. Townly, of Michigan, had previously made the same discovery. He also invented the solar wax-extractor about the same time. He was vice-president for several years of the N. A. B. K. Society; president of the Iowa State B. K. S., and honorary member of the Michigan State B. K. S. Mr. Poppleton is a careful observer, doing his own thinking, and adhering to plans which he has found successful.

Mr. Poppleton is of spare figure, hardly up to medium size. His very pleasant manner is only a fair index of a genial and loving spirit that, in an unusual degree, strives to put the best construction on the conduct and motives of every one.

Bowling Green, Iowa.

MRS. M. GEORGE.

And so it transpires that friend Poppleton was first attracted to bees by H. A. King's publications, from Nevada, Ohio. I myself first got hold of Langstroth's book, but I very soon came to King's text-book and a circular in regard to the American hive. These two last aroused my enthusiasm to such a pitch that nothing would answer, short of a hurried trip to Nevada. I found friend King there, and got my first glimpse of a real bee-hive factory. Every bee-keeper who has heard friend Poppleton talk at our conventions must have been impressed with his very thorough and earnest study of every minute phase of our favorite industry.

Even when I read his writings I am astonished to see how closely and critically he has looked into every obscure point and corner; and his invariable success as a honey-producer attests to the excellence of his wisdom and judgment. We are greatly indebted to him for the solar wax-extractor, as well as for many other things. Perhaps it would be well to say, that, since the writer makes no mention of it, Mr. Poppleton is now in Cuba, taking charge of some 600 or 700 colonies for M. Dussaq, Apartado 278, Havana. Friend Poppleton's experience with bees not only covers the temperate climate, but Florida and the island of Cuba. You will notice that he is one of the respondents to our Question-Box, and he is eminently well fitted to impart almost any information in regard to bees.

THE JAPANESE BUCKWHEAT.

PROF. COOK ON THE CARDINAL FLOWER, ETC.

FRIEND ROOT:—Last spring I purchased of you four quarts of the Japanese buckwheat. I sowed the same on new ground. It ripened earlier than the common kind. The bees worked on it from morning to night, but they did the same on common buckwheat. This is an uncommon occurrence here. I think it was due to the moist, cloudy weather. The buckwheat filled well, but I saved only two bushels of seed. We had a week of warm, rainy weather immediately after it was cut, and it sprouted so badly that I saved less than half the seed. But what I saved is nice. I am convinced that it is ahead of the common kind.

THE CARDINAL FLOWER.

Prof. Cook's article on the cardinal flower interested me, as I am making a special study of bee-botany. I know friend Cook is unprejudiced and good-natured, and will not feel offended if I tell him that there are some things in his article (see p. 926, Dec. 1, 1888) that are not clear to me. Without doubt it is due to my ignorance, or else to my observation of the flower not having been thorough enough. The tube formed by the filaments and anthers is two or three times the length of a bee's tongue, and the nectar is secreted at the bottom of the tube by glands which are on the ovary near the base of the style. There is no opening into this tube except at the top, after the stigma has pushed its way up through the united anthers. Am I not right, friend Cook? Now, the point which puzzles me is as to how the bee gets the nectar. Then from the manner in which the bee must necessarily alight on the flower, I can not see that she would do much better work in fertilizing the flower than those upper flowers which shed their pollen, when the lower ones are most in need of it. To be sure, it would be chance work, but I can not see that it would be any more so than the work of the bee in that line. If I'm in error, please correct me. I admit frankly that I am not as well acquainted with the cardinal flower as I hope to be. The place neighbor Hilton spoke of is only ten or twelve miles from here, and I hope to visit there next season when the cardinal flower is in bloom. In this immediate vicinity it is rare, and grows only in low moist places.

Prof. Cook, you, an entomologist, tell us that the

honey-bees do not bite through the corolla tube of flowers to get the nectar. Very good! But on page 188 of the A B C (or 204 of the last edition) friend Root, a practical bee-keeper, tells us that they do bite through at least one flower, and speculates on the probable fate of the plant. Now, when learned men disagree, what are we common fellows going to do?

THE WILLOW HERB.

Last season I received most of my light honey from the great willow herb, which grows here profusely. It thrives best on high ground, especially where fire has run, hence the commonly known name of purple fireweed. Those who do not know the plant should not confound it with the fireweed which blooms just before the fall frosts. The willow herb is known by a great many names, such as Indian wickopee, deer pink, Indian pink, and purple fireweed. It grows from 4 to 7 feet tall, without branches, and blooms in July and August. There is a smaller variety, which grows on low wet ground, whose stem branches.

Fremont, Mich.

WILLIAM E. GOULD.

COMMENCING THE SEASON.

HOW TO PREPARE FOR THE HARVEST.

OUR first work after getting our bees out of winter quarters is to know that each colony has honey enough to last them from two to four weeks, the latter being preferable to the former. Unless bees have plenty of honey at this time of year, brood-rearing will go very slow, for bees are very frugal when they think there may be danger of starving in the near future; and as brood-rearing requires much honey, it will be seen why honey for four weeks ahead has an important bearing on the honey crop which we hope to obtain. The brood reared during this month and the latter part of last month, constitutes the working force which gathers honey from white-clover, so if we are to get a crop from that source we must leave no stone unturned which looks toward that end. Looking toward this I go over all of my colonies some cool morning, and all which do not occupy six spaces between the combs, with bees, are shut on to as many combs as they have brood in, by means of a division-board, as soon as it is warm enough to work with them. If they are very small, so as to have brood in only one or two combs, and small patches at that, I take away all extra combs, so as to take precaution against robbing; but if they are a fair colony, I leave the extra combs the other side of the division-board, so the bees can carry the honey over as they need it for brood-rearing. Contract the entrance to each colony as soon as they have their first flight in the spring, to suit the size of the colony, giving the very strongest not more than three inches in length of the entrance, while the weakest should be contracted so as to let out but one bee at a time. If, after all precautions, the bees get to robbing, I know of no better way than to carry the colony, that does not protect its stores, into the cellar, and leave it a week or so, or until the bees are getting pollen freely, when they will rarely ever attack them again unless they are so weak as to be worthless. Having all of my bees fixed as above suggested—that is, they all have

honey enough, and those occupying less than seven spaces between the combs shut on to only as many combs as contain brood, our next work is to increase this brood as fast as possible. There is little if any thing gained now by handling the bees, only to supply them with honey, should any be short; but as soon as it comes fairly settled warm weather, I think a gain can be made by spreading the brood to more than pay for the labor required. When such weather comes, the way I work with the strongest colonies, those not having any division-boards, is to change the brood-nest right over; that is, to place the central sheets of brood, or those having the most brood in them, in place of the outside ones, or those having the least brood in, placing those having the least brood in the center. Thus we get every frame full of brood that has any brood in it at all. Frequently we will find all of the brood in one end of the combs, the other end of the frame having none in at all. When such is the case I simply change ends with every alternate frame, which brings about the same result as before. The next time over, or in about a week more, I take one frame from the outside of the brood and place it in the center, and so on till all of the nine frames are filled with brood. Those that are contracted with the division-boards are kept as they are until they have every available cell for brood filled with the same, when an empty comb is placed in their brood-nest also.

If I wish to build all up to strong colonies, I take from those having their hives full of brood a frame of hatching bees, and give it to the strongest of the weaker colonies, and place an empty comb in place of the frame of hatching brood taken, and so on till all are built up to strong colonies, each having a hive full of brood; that means, have the brood so it comes out to the side-bars of the frames; even the cells bordering on the bars at both sides and top should have brood in them, and do not stop short of this. If you have queens that will not keep the hives filled with brood like this during the month of June, mark them, and as soon as convenient replace them with those that will. If you do not wish as many colonies of bees as possible, I will tell you of a plan of using those colonies that needed a division-board, which has been very profitable with me in the past.

As soon as those having five frames have them filled with brood, take from them a frame of hatching brood and give to the next strongest, say one that has four frames, and put an empty comb in the place it came from, and so keep working till you have each hive contain five frames completely crowded with brood. A queen that will not keep five Gallup frames, or their equivalent, crowded with brood is not worth keeping at all, and should be superseded at once. If you succeed as you should, all will have their five frames full about the 10th or 12th of June, in this locality. Now go to No. 1 and open it, and look the frames over till you find the queen; and when you have found her, set the frame she is on to one side, then take the four remaining frames and all the bees to No. 2. Spread the five frames in No. 2 apart, so as to set the four frames brought from No. 1 in each alternate space, made by spreading the frames in No. 2. Close up No. 2 now, and you will see that, in ten or fifteen days, it will be one of the strongest colonies you have in the yard. Returning to No. 1, which we left with the queen standing outside of the hive, we

place the frame in the hive close to one side; and after putting in an empty frame next to it, the division-board is adjusted, when we have a nice nucleus, to be used for any purpose we may desire. I generally use it for building worker comb or for rearing queens according to my needs, and think for either it can be made of more profit than to take away the queen and unite all of the bees with No. 2, as some who have written me conclude is a better way.

I have given the latter part of this article before; but of late I have had to answer so many questions regarding it, that I thought it best to give it again. I hardly think it advisable to put on boxes, in this locality, in May; but further south they should be put on as soon as any of the hives are filled with brood. Of course, each one can use the principle described, whether north or south, and vary the dates to suit their locality. The plan as above given is the best way to get the bees ready for the harvest, in my opinion, after having tried multitudes of other plans, none of which proved as good.

G. M. DOOLITTLE.

Borodino, N. Y., Apr. 13, 1889.

SHALL WE PAINT OUR HIVES?

NOTES ON DOOLITTLE'S ARTICLE, PAGE 217.

UNTIL I read Mr. Doolittle's article on page 217 I had never, I think, heard it claimed that unpainted hives had any advantage over painted ones. His experiment with a number of colonies in which those in the former style of hive came out so much better than in the latter is experience, and can hardly be gainsaid. I have always claimed that the testimony of experience is worth entire volumes of reasoning. But, did he have chaff cushions, or any kind of a good absorbent over the frames? I feel certain that, when that part of the matter is properly managed, all trouble as to moisture will disappear. When I prepare my bees for winter I put about two thicknesses of burlap over the frames, and above them about four to six inches of chaff. The chaff is in boxes, the sides of which are made of boards with a burlap sheet tacked on to the bottom, and the top left open. These chaff boxes rest upon the brood-chamber in such a way as to more than completely cover the frames, so that I think no heat is ever lost. For experiment I have sometimes put on enameled cloth in place of the burlap, in which case I have found them dripping with water, and the combs moldy. But when I use the absorbents, as described above, I have no such thing. I often find the ends of the sheets and chaff wet; but immediately over the cluster, all is dry. It is very little condensed vapor I ever find, and that in the remotest end of the hive. I leave the winter packing above the frames on until the weather is warm and the stocks are quite strong. I think my upper absorbents are about as near perfection, so far as they go, as can be obtained, and obviate all difficulty concerning moisture. That done, I think it not hard to establish the superiority of painted hives. I admit I have not tried, unpainted hives very much. I had one when I commenced bee-keeping, and it, though not an old one, was all warped and cracked, just like any other unpainted box when exposed to the sun and weather. Judging from that, and the characteristics of pine lumber in

general, I considered the matter settled, and went to painting my new hives all white. In behalf of paint, the point of *perfection* must be added to that of durability. But those are not the most important items in the case, after all, I think. White does not absorb heat. It is as a shield from the piercing rays of the summer sun that I want my hives painted white, as many of my hives stand right in the sun. Some bee-keepers, A. I. Root, for one, have given us proofs that, when hives are painted white, the interior is less affected by the heat of the sun than those painted any other hue; and the difference between white and unpainted hives must be the same in kind if not in degree.

One other point: If porous walls allow moisture to pass out, must they not allow it to pass in likewise? I know that the interior of my painted hives is much affected by the dryness or dampness of the weather, while those in the sun are perceptibly dryer than those in the shade. Must not the unpainted (and consequently porous) hives be even more sensibly affected? If I am wrong, I am willing to be set right; but so far, I am satisfied that it is better to adhere to painted hives.

GEO. F. ROBBINS.

Mechanicsburg, Ill., Mar. 22, 1889.

Very likely, friend R., unpainted hives, during a very wet, rainy time, would get more damp and soggy than painted ones; but when the sun comes out I think they will dry out, outside and inside, quicker. In the early spring, when the bees need all the benefit they can get from the sun, a black, unpainted hive would certainly secure more warmth; but when the great heat of the summer sun becomes an objection, it would be just the other way. A careful, enlightened, intelligent bee-keeper will, as a rule, have not only his bee-hives, but his implements and every thing else, including house and barn, kept well painted, while the slipshod don't-care old foggy would be pretty sure to have every thing unpainted; therefore paint indicates the character of the man. I should hesitate some about wanting my hives to present such an appearance as unpainted ones usually do.

WOODEN COMB.

PROF. COOK TELLS US THAT IT IS ALREADY IN PRACTICAL USE.

MR. EDITOR:—You, the publisher of a standard work on potato culture, and most readers of GLEANINGS, will, at the mention of Aspinwall, think of potato-planters. The Aspinwall potato-planter is the invention of Mr. Aspinwall, of Three Rivers, Mich. Mr. A. is not only an inventor of high rank, but he is a refined Christian gentleman, as every one who meets him will at once believe upon looking into his face. How much there is in a face! It is indeed the mirror of the soul. I think, friend Root, you and I once talked this over. In Tennyson's "Elaine," Launcelot, when first seen by the beautiful Elaine, is thus described:

The great and guilty love he bare the queen,
In battle with the love he bare his lord,
Had marred his face, and marked it ere his time.

It seems as if nature had made it so for our protection. The evil heart is very often betrayed by the face. So a clean, pure face as surely indicates

a refined and manly heart. I felt drawn to Mr. Aspinwall when I first met him, just as you and I did to our friend Mr. Cowan. I always feel richer when I become acquainted with such people. Mr. Aspinwall is also a practical bee-keeper, and this is why I am writing of him. He uses a modified Quinby hive, and believes in it. Indeed, he knew Mr. Quinby well, and, like all who knew this excellent man, he can not speak in too high terms of him.

Mr. Aspinwall has invented, and put into practical operation, wooden combs. These are simply boards with round holes the size of brood-cells, cut from opposite sides to the center. Mr. Aspinwall has tried these, and says they are accepted by the bees both for storing and breeding. He puts these in hot wax to soak, so they are covered with a very thin coating of beeswax. He is going to send me a hive fully stocked with these wooden combs, to try. He is sure I will like it. As the partitions between the cells are thick, the combs have to be larger or more numerous in the hives than are natural combs.

THE ADVANTAGES.

Mr. Aspinwall claims that these are superior, as they are strong, durable, inexpensive, perfectly under our control, warm, and so better for winter. As the size and depth are under our control, we can make the combs worker, drone, or store combs, at pleasure; and as the bees can not cut the cells down, they must accept what we give them. Mr. A. says that the queen can not lay in deep cells, thus we can have cells of worker size, and yet they will be only store combs. If combs are $\frac{3}{8}$ of an inch apart, then queen-cells can be made on the edges only, and can be easily seen or found, as the bees can not gnaw the comb away. Mr. Aspinwall has secured a patent on this, which is surely his right. If of no value, then we need not use it; if of value, then we ought to pay him, as it is his invention; and without his thought and work we should have known nothing of it.

I am principally interested in this wooden comb, as I see in it a chance for some very interesting and I think valuable experiments. For instance, our friend Mr. S. Cornell thinks that bees can not live on the carbo-hydrates alone. I believe Schonfeld holds the same opinion, and argues that the nitrogenous material may come from the larval excreta and exuvia which collects in the cells in breeding. From my experiments with very new clean comb I have been led to the opposite opinion. With these wooden combs we can demonstrate the truth or falsity of the position held by the above-mentioned gentlemen. We can use wooden combs in which no brood has ever developed, and combs filled in the upper story above the brood-nest, where no pollen would be stored. Thus we shall have a clincher. Now, I feel perfectly certain that bees thus wintered will not only live but thrive. I think this is in unison with physiological laws. True, all animals need nitrogenous food. But in winter bees are so quiet, and the functional activity so slight, that the small amount of albuminoids needed is in the blood. So with the almost pure carbonaceous food—honey, or, better, pure sugar syrup—they are strong and healthy. Of course, these combs will be very heavy. They may not be practical or satisfactory, but I shall be glad to try them for the sake of experiment and curiosity, if for nothing more.

Agricultural College, Mich.

A. J. COOK.

We are very glad indeed, friend Cook, to

know that Mr. Aspinwall, of whom we have all heard more or less, is a bee-keeper as well as an inventor. I heartily agree with your remarks in regard to our faces being an index to our character; therefore if a man's face is not a good one it is, at least to a large extent, his own fault. I will try to keep it in mind next time, when I feel inclined to scowl and look cross.—If I am correct, father Langstroth has the credit of being the first one to suggest using combs made by boring holes of the desired size and depth close together, in a board. I have been too busy to look it up, but I think that in one of the earlier volumes of GLEANINGS the suggestions were put in print. Such combs have been tried by different ones, if I am not mistaken; but the decision was that they were too heavy; and without exceedingly expensive machinery it would be impossible to get as many bees to the square inch as nature does. More than ten years ago, myself and Mr. Washburn discussed how a machine would have to be made in order to make these perforated boards so rapidly they could be sold at a price within the compass of the average bee-keeper's pocket-book. We have combs with a wooden base now in our apiary; the base was embossed by running it through a foundation-mill. One objection to it was, that it took so much beeswax to soak up the wood.

BEE-HUNTING.

HOW TO CLIMB THE MONARCHS OF THE FOREST.

MR. ROOT:—By to-day's mail I send you a photograph of a large poplar-tree, which I climbed recently by means of spikes and staples. To prevent the possibility of falling I put a belt under my arms. To this I attached two chains. At the end of each chain is a snap. My method of climbing is as follows: After ascending the ladder as far as I can go I drive into the side of the tree a large bridge spike, far enough into the wood to hold my weight. A little further up I drive another spike. In between the spikes I drive the first staple, and to this I attach the first chain by means of the snap, and ascend by the nails as far as the chain will allow me; I then drive another staple, and attach the other chain, and next loosen the lower snap. After driving in more spikes, I again ascend as high as the chain will allow me, and attach the other chain to another staple. In this manner I can make my ascent with perfect security.

The tree shown in the picture is 7 feet in diameter at the foot. If you will follow all along up the body of the tree, just above the crotch on the right limb you will see your humble servant, 88 feet from the ground. The tree stands close to the Black River, in a graveyard, and from it I obtained 50 lbs. of honey. Your climbers are excellent for small trees, say from two to three feet in diameter; but the tree illustrated has such a rough and uneven bark, and is so large, that it would be difficult to climb it without the aid of spikes and the staples I have mentioned. On account of the large knots it would be impossible to use a rope, or something similar, to hitch up by climbers, as described in the

A B C book. Knots are not in my way when I use spikes and staples.

DERRINGTON'S DEVICE FOR CLIMBING VERY LARGE BEE-TREES.

Next summer or fall I am going to climb what is called the "Big Bee-tree" that stands on the bank of the St. Francis River, down in the sunk lands. This tree has 15 swarms in it. It is a cypress, 14 feet in diameter at the foot. The bees work in at the body in a stream as large as a man's limb. I shall burn brimstone in the tree, and so kill the bees, as they are very bad. I have bees at home, and do not care to save any of these.

GREEN DERRINGTON.

Poplar Bluff, Butler Co., Mo.

Well, friend D., you have gone and done it, and no mistake. If anybody thought you were spinning a big yarn when you talked about taking bees from a tree 88 feet from the ground, they would give in when they came to look at your picture, for the picture, without question, is a genuine photograph of an awful big tree, with a man perched away up amid its limbs. With a harness such as you describe, and myself securely hooked fast, and held there by stout chains, I do not know but I might consent to climb such a tree; for one could not very well fall, even if he tried to, as you describe it. It seems to me, however, it would take a good deal of work and quite a little time to get up that distance. Ernest suggests that the load of spikes you are obliged to carry along might pull down pretty heavily, especially on the start. Did the 50 pounds of honey pay for the time and money invested? Never mind, even if it didn't. You "got there" and captured the bees, any way.

ORANGE-BLOSSOMS.

DO THEY PRODUCE HONEY?

HAVING followed, with deep interest, the account of your interesting trip to California, in which a great many things bring to my mind what I see here every day, I should like to say something about our orange-blossoms in Florida.

It is no surprise to me that, in California, orange-blossoms give no honey, the land being so dry that it has to be irrigated, and what little sweet there might be on the flowers is carried off by the dry atmosphere. In our State, and especially where orange-groves are situated, there is a continuous drainage of water, at a depth of two to five feet, under the very roots, from lake to lake, all the lakes being on different levels, and from these to rivers. The lakes are very numerous all over. From my house, on the veranda I can count and see four lakes, one of them two miles long. Our orange-trees being thus irrigated by the most wonderful system of natural drainage, are fully supplied with the water needed, and keep their blossoms so moist with sweet nectar that there is actually a small drop of honey in every bloom, which is eagerly sought by the bees. The atmosphere, owing to our proximity to seas and lakes, is always moist, and thus prevents a too rapid evaporation of the sweets on our blossoms. The yield seems to be continuous from morn till eve, since Feb. 15th. I have seen orange-trees, while blossoming, so covered with bees that one might easily have thought there were not one, but half a dozen swarms on one single tree. Our bees swarm during the yield of orange-honey, or, if increase is not desired, they can be worked

for producing what I call, after having eaten honey all over, the whitest, as well as the finest-flavored honey in the world.

J. B. LAMONTAGNE.

Orlando, Florida.

What you tell us is surprising. Notwithstanding all that has been said in regard to Florida and the orange-orchards, I never before heard anybody speak of seeing bees in the orange-trees so that they made a noise any thing as they do in our apple-trees. Is it not only during an occasional favorable season that you have reports like the one above? One other thing: We have had two samples of orange-blossom honey from Florida this spring; and the last sample of comb honey is certainly equal to the California white sage, or to any thing else that it has been my good fortune to taste, in the way of honey. One of the friends sent us a sample that was passed around among the printers, and, if I am correct, they agree exactly with me.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

PROPER DISTANCE IN SPACING COLONIES.

WHAT distance must separate two stocks of different blood to keep them pure? If I should remove the queen from a colony, and after a few days should be compelled to return the same one, is there any liability that the bees would be hostile to her? Will feeding meal from a single vessel start robbing among the bees? Will setting hives that are all exactly alike, in a straight row six feet apart, be in any way a disadvantage to the bees? Which is the best way to arrange an apiary of less than fifty hives?

Muskegon, Mich.

E. HILE.

Queens are apt to go beyond the immediate neighborhood of their own hives to be fertilized. To keep the two races distinct they should not be nearer than a mile and a half. Two miles would be better. Feeding meal will never cause robbing. It is not exactly advisable to put hives in straight rows, with the entrances all one way. It is apt to result in some confusion to the bees, and particularly so to young queens. Hives as arranged in the A B C book make a very good arrangement. See "Apiary," in the A B C book.

LOSS OF QUEENS IN WINTER; LOSS OF COLONY;
WHICH MAKE THE BETTER WORKING COLONIES,
THE LARGE OR SMALL CONSUMERS
WHILE IN WINTER QUARTERS?

I have to chronicle the loss of all late fall-raised queens. They hatched out the first week of October, and had ample chance of being fertilized. They were produced in an easy, off-hand sort of way, and they died after the same fashion. I knew they were gone in January, but I had hopes that their bees might live till I could re-queen them. All such colonies died early in March. I do not wish to say that queenless stocks will not winter, but I am certain that, had those queens lived and been mated, I should not have lost one stock. Had all my queens died in winter, all my bees would have been dead now. All had dysentery alike, and all such died. But my vigorous queens began laying in December,

and brood-rearing, less or more, was kept up; and by the time all the old sickly bees were dead I had a nice little batch of young healthy bees in each stock when March came. Phenomenal weather—did you ever know the like? Natural pollen the 15th of March, and brood in from one to three frames each. What will be the outcome of all this? My sickly bees consumed enormous quantities of honey.

I am surprised at some of the answers to Question III. Yet one thing is only fair to these gentlemen; and when I reflect that their homes are scattered throughout the States I am disposed to be charitable. I am no bee-keeper in a scientific sense, but I know enough to know that here in Logan Co. (Central Illinois), the less stores an average colony consumes during a four-months' repose, the healthier will such bees be in spring. Of course, all agree that, after natural pollen begins to come in, the more they consume the better. My bees ate fully 30 pounds each stock this winter, and I shall have to feed; yet my report shows that they gorged themselves to death. I bought, last fall, 4 miles from here, a stock of black bees in a box hive. It was a large hive, and would weigh, in November, between 80 and 100 lbs. I went for it the last of February. I was delighted. The stock was just perceptibly lighter, packed full of bees, and actually not half a pint on the bottom stand. I looked narrowly all around the hive, but no dead bees anywhere. I say this is perfect wintering.

Beason, Ill.

JAMES HAMILTON.

Friend H., it seems to me you are a little hasty in your conclusions. I do not know that I would advise trying to winter a colony that raised a queen which failed to be fertilized. You see, in such a case they were some time queenless before winter commenced. The circumstances are quite different from that of a colony where a good queen was taken out and sold, say in November. In the latter case I do not think there would be a bit more danger of dysentery than if the queen were left with them. In fact, several observations seem to indicate that such queenless colonies are less liable to dysentery or spring dwindling.

DRONES FOR EARLY QUEEN-REARING.

We have seen mention made of securing drones early, so as to commence queen-rearing earlier. Bro. Doolittle can secure the drones early, but not the queens, so he sends south for virgin queens. We can get queens before we can get the drones in this climate, so we send south for drones. We had very fine weather the last two weeks in April, and can commence for queen-rearing to have them hatching by the 10th of May. We should have to have drone eggs laid by the first of April, to have drones to be of any service by the 15th of May. This is impossible with us here. We have for the past two years made arrangements with Mr. P. L. Vialon to furnish us by the 20th of April with a four-frame nucleus made up of two frames of drone brood, nearly ready to hatch; by this means we have them in time. By getting drones from a reliable person who will take pains to have them raised from the best stock, we also get new blood in the apiary, as well as early drones. We prefer to get them in the brood state, but have not heard any one so express themselves. Probably this is original with us. In the March number of the *Queen Breeders' Journal*, advice is given to purchase drones

by the pound, saying that they would likely be worth \$3.00 per lb. Getting drones by the pound would be a handsome job for both parties, the sender to catch them and the receiver to save them from being killed, as that many drones turned in on a colony would not be agreeable. Our way of managing a nucleus received with drones is to make the nucleus queenless when putting them in a new hive, and give them a frame of hatching worker brood. They can be kept queenless quite a while by giving young brood at times until plenty of drones are hatching from other colonies in their season.

JNO. NEBEL & SON.

High Hill, Mo., March 28, 1889.

THE ENTRANCE TO THE SIMPLICITY.

I should like to ask if there is no need of an alighting-board; and does not drawing the hive forward on the bottom-board make too long an opening, giving better chance for robbers, etc.? Please tell me how you space the frames in the hive. Is it not troublesome to change them about till they are just right?

E. CALVERT.

Nashville, Tenn., Apr. 1, 1889.

When robbers are troublesome we would use an alighting-board, as described in our price list and in the A B C. With an alighting-board you have the entrance more perfectly under control than in any other way I know of. For strong colonies no alighting-board may be needed. We space the frames in the Simplicity hives, simply by placing the end of the fingers between the supports at the ends; and one who is in the habit of doing it will do it without thinking of what he is doing, and almost as rapidly as his fingers can touch them.

A WASP'S NEST: DO THE YOUNG LARVÆ CAP THEIR OWN CELLS?

Last summer there was a wasp's nest in my shop. I knocked it down and laid it away, and the larvæ capped themselves over. I uncapped them, and in two or three days they were capped again. I uncapped them four or five times, and they replaced the capping. But each time the capping was thinner and whiter. You will say that the old wasps did it, but they didn't, for I shut the nest up in my shop, and worked there every day. Will the larvæ of the honey-bee do the same?

E. J. SHAY.

Thornton, W. Va., Apr. 8, 1889.

Will Prof. Cook please answer?

BEEES AND SORGHUM SYRUP.

In GLEANINGS for April 1 were some comments upon feeding sorghum to bees, in lieu of honey, as a support until the honey-flow should come in. I can not conceive how any bee-man could successfully do this, unless in connection with other food; bees will cluster around an empty sorghum-barrel in which the staves have absorbed all the moisture, and draw from the saturated wood, or will sip of the fresh cane juice before any fermentation has begun; but sorghum molasses they will pass by in disdain, as it were. Last fall was very dry, and honey very scarce. The mill was visited a little by the bees. The fall of 1887 the season was extremely dry, honey crop short, the crusher was thronged, and thousands of bees were killed. Water was so scarce that it was sold by the barrel. We made a trip of four miles for all we used. Some hauled it ten miles, in tanks holding four or five barrels. The bees

were compelled to drink the juice, yet they did not disturb the new molasses. In my evaporating-room the juice tank and buckets would be covered, the interior part of the building was like the center of a moving swarm, and yet they did not disturb the condensed sweet.

You are aware that there is an acid principle in sorghum that is quite plainly discernible to the taste, and I think this is not relished by the bees; and from the fact that I've been handling both bees and sorghum for quite a number of years, and the two not 200 feet apart, I am assured that bees would come out in worse shape than Dr. Tanner in his 40-days' fast, if any one should attempt feeding entirely upon it.

W. N. ROOT.

Assumption, Ill, April 10, 1889.

While all you say is true, I have known bees to take with avidity a very good article of sorghum syrup, and syrup made of a pretty good article of brown sorghum sugar is taken by the bees just as well as any brown sugar, for all I can see. Of course, they will not use it when they can get better. Enough sorghum molasses has been fed, however, to make it pretty clear that it does not answer at all for winter stores.

HOW WE CURED FOUL BROOD.

You have not as yet (at least I have not seen it) published the method by which you cured, or exterminated foul brood from your apiary. Will you please tell me how it was done? We have the disease here, and I want to exterminate it this spring. I have the A B C plan, Cheshire's, McLain's, and Kohnke's methods. Is there any other? Send me Jones' cure and your own, please.

H. SMITH.

Ionia, Mich., Feb. 25, 1889.

The method by which we cured foul brood is the one given in the A B C book. If you have either the edition of 1887 or 1888 you will find it under the head of Foul Brood. The editions before 1887 do not contain the plan; not having had any experience prior to that time, we simply gave two or three methods of curing foul brood which were said to be reliable. The only plan which we could make work successfully is the one preferred by D. A. Jones, so that the method which we used differs in no important particular from that of Mr. Jones.

TO CONTROL INCREASE.

Would you advise controlling increase of bees, in the following manner, taken from an article by quite an experienced bee-keeper?

"Suppose colony No. 1 to send out a swarm. I move hive No. 1 back from its old stand about 3 ft., and place an empty hive, filled with combs, where No. 1 formerly stood. I hive the new colony in the empty hive, filled with combs, where No. 1 stood. Then shake all the bees from frames of No. 1 into the new swarm. I shake the new bees, that hatch from No. 1, into the new swarm every day, until another colony sends out a new swarm, when I use hive No. 1 for an empty hive to receive the second new swarm, and treat No. 2 the same as No. 1.

Ellsworth, O., March 26, 1889. L. B. B. BINGHAM.

The plan you give is one that has been often recommended through the journals, and answers very well, only I should not want to shake the bees off those combs every day, as you suggest, for there would

then be none to take care of the brood, to keep it from chilling and starving, until the second new swarm came out. If you are sure of having swarms every day, it might answer; but otherwise you would lose all the sealed brood left when colony No. 1 swarmed. When a natural swarm comes off, there are always bees enough left in the hive to take care of the brood. I think that these bees had better be left there. Where one has more bees than he wants, however, and does not care if the brood does die, this might answer, to get as much honey as possible, regardless of loss of bees.

THE SHRUB THAT BLOSSOMS THROUGH THE SNOW.

You inquire about forsythia. It is a cultivated shrub that is referred to, I think, and it has been known for at least 20 years to be a pollen-plant in this State. It will be in bloom from April 1st to May 1st, according to season. It is good; it looks well with its load of rich yellow flowers on the bare green twigs, and before any other shrub blooms. Bees work on it well. Its abundant bloom is fine too. I can send you a bundle of cuttings if you want them. It is as handsome a shrub as a Japan quince.

H. L. JEFFREY.

New Milford, Conn., March 22, 1889.

Thank you, friend J.; but it now transpires that we have the forsythia in our own dooryard. We never knew it to blossom, however, when the snow was on the ground. Its yellow flowers usually come out the last of April or first of May. We should not have recognized it, perhaps, had not one of our subscribers sent us some twigs by mail, directing us to put them in a tumbler of water, saying they would soon blossom, which they did, and I at once recognized it. It does not seem to do well, however, very much further north than we are. See the following:

FORSYTHIA VIRIDISSIMA.

Over thirty years since, in a bale from Ellwanger & Barry, of Rochester, N. Y., was one of the above-named shrubs. It blossomed the next spring; that is, a small part of it. In three or four years it was increased to several, and each one would have a little branch or two blossom every spring, just enough so that one could imagine what a beauty one would be in full bloom. I tried "protection" and cellar "wintering" on them, but with no better success; and after eight or ten years I became disgusted, dug them up, and consigned them to the flames. From 15 to 30° below zero was too much for them. I kept bees, but never saw one on the blossoms. The shrub is probably kept in most nurseries.

JAS. H. ANDRUS.

Almont, Mich.

THAT FINE QUALITY OF CALIFORNIA HONEY; MORE ABOUT IT.

Friend Root:—In company with the rest of the unvisited Californians, I was somewhat disappointed in not seeing you while you were in the land of booms. I had saved out about a ton of the X quality of comb, of which I sent you a sample case last fall. In acknowledging the receipt of the case you spoke of the honey as the finest, both in taste and color, that you had ever seen, and said that you would give "considerable" to know what feed would produce such honey. Well, it was gathered from alfalfa blooms, pure and simple, all three

grades, the darkest during cooler nights, the lightest during the warmest nights and hottest days (110° in the shade). Remember, too, that this beautiful white honey was produced in the San Joaquin (waw-keen) Valley, and not in the mountains, and that I have taken the first premium whenever I have exhibited in competition with the "white sage" and other grades of California honey. Did you find any thing superior to it, while on your pleasure-trip?

I hope that both yourself and Mrs. Root will find time to visit us when you come to the State again.

LOUIS W. BURR.

Bakersfield, Cal., March 18, 1889.

Friend B., we have never seen any nicer honey to look at, and, I think I may add, finer to the taste, than the samples you sent us; and I am very glad indeed to know that it came from alfalfa and nothing else. But, strange to tell, when I inquired of bee-men in California, near the great alfalfa fields, I do not remember one of them who told me they got any honey at all from it. They seemed to treat the whole thing as a sort of myth. Our older readers will remember that the alfalfa that we tested here on our honey-farm did not yield enough honey so that a bee was ever seen on it. This matter is interesting, as quite a few bee-keepers have been talking of sowing alfalfa, mainly because it is a honey-plant. Now, will you tell us something about it in your locality? Does it yield honey every year? and is it possible or probable that it will amount to any thing for honey when small patches are sown, the same way we sow buckwheat for bees, for instance?

NOT IN FAVOR OF QUEEN-EXCLUDING HONEY-BOARDS.

When I received your price list yesterday I looked through it as soon as possible to see what you had that was new and useful; but when I came to the zinc honey-boards I stopped to consider (as Eli Perkins used to say). Well, I have had considerable experience with those things—about ten of them. I can't call them honey-boards or queen-excluders, or any thing very good. They were on the common L. hives, and every brood-nest was above the queen-excluder, and all were very weak—much weaker than other hives in the same apiary. One of the excluders was so full of dead drones that a common bee could scarcely get through it. The poor fellows were all hung by their necks; and when I lifted the zinc up it looked more like a large brush than a honey-board. A man ought to be taken up for cruelty to animals who would use such a thing. I use the Heddon slatted honey-board. Friend Wilkin says he don't believe you dare publish this; but I don't care; that is just what I think of zinc honey-boards.

L. E. MERCER.

San Buena Ventura, Cal., Mar. 15, 1889.

Friend M., you tell our friend Wilkin that he must scrape up a little more charity. We not only *dare*, but we *want* facts, both for and against every thing we advertise and sell. In all that has been said for and against the perforated zinc, we do not remember to have received a report like yours. In the Alley drone-trap we have seen a few drones caught in the manner you describe; but we concluded that the poor fellows had worried so long to get through that they died in the attempt, hang-

ing, as you say, by their necks; but we can not understand why the brood-nest should be above the honey-board. The new perforated zinc which we send out will exclude queens. Some of the zinc which we sent out two or three years ago was a little defective, some of the dies having been flaked; but this we remedied by making new dies and building a new machine. It is possible that you have some of this old zinc; but we venture to say that you would have no trouble with our new zinc. If, in your next order, you will refer to this page in GLEANINGS, we will send you ten new zinc queen-excluding honey-boards, wood-bound. We shall be pleased then to have you report to us after trying it. Please remember that there are a great many good bee-keepers—some quite extensive ones too—who use and advocate perforated zinc.

LARGE OR SMALL BROOD-CHAMBERS.

I will crack Mr. S. A. Shuck's nut, in GLEANINGS of April 1, page 259. Your frames were too shallow for their length. A natural, good-sized brood-nest, embraces a sphere of about 10 inches in diameter; so if your frames were 10 x 10 or 11 x 11, you would have had better success. I have used 10 x 10 frames for several years, and like them very well; but for a more northern latitude I think they would be rather small, and think 11 x 11 the better size, or, say, the Gallup size, 11¼ x 11¼, as that is already largely in use, I think. J. C. MELCHER.

O'Quinn, Tex., Apr. 10, 1889.

If your object were to raise *bees*, without any regard to getting surplus honey in sections, no doubt a square frame would be best; but I think a perfectly round one, in the form of a barrel-hoop, would be better still; but if the bee-keeper wants to get every drop of honey possible into the sections, and does not care particularly for increase, then I feel satisfied that he wants a frame something like the one that father Langstroth gave us years ago—a frame that will permit the section boxes to come down quite close to the heart of the brood-nest. Some of the friends want them even shallower than the Langstroth frame. The great bee-keeping world seems to have so settled down to something like the Langstroth frame, especially where we want comb honey, that I think we might as well accept it as the standard.

SUPERSEDURE; AND IS THERE ANY PREVIOUS INDICATION OF IT?

1. How can you tell when bees are going to supersede their queen? 2. If a worker bee—an imperfect female—loses its sting after using it, and its life, why does not a queen—a perfect female—share the same fate under similar circumstances?

Atlanta, Ga., April 8, 1889. T. E. HANBURY.

1. We do not know of any way to tell positively when bees are about to supersede their queen; but as a rule we may say that queen-cells started at some other season than swarming time rather indicate it. And if at the same time the queen does not seem to be producing very much brood, then we have every reason to think she is about to be superseded. It is my opinion, however, that queens are often superseded when there is no apparent reason. 2. Worker bees,

when they sting each other, do not generally lose their stings. The queen rarely ever stings a human being; almost the only occasion when she uses her weapon is to sting a rival. If the *worker* bee does not lose its sting when it stings one of its fellows, it is not at all likely that the queen would lose her sting when she uses it upon another queen.

SETTING SAWS; HOW TO DO IT AND HOW NOT TO DO IT.

I noticed in GLEANINGS for Feb. 15, an article by William Young, inquiring how to set a circular saw. Now, if he takes my advice he will use the spread and spring set. Spread the teeth just enough to keep the tooth full width, or a little wider, as the saw will run lighter. Do not set them with a hammer, as it will reduce the width of the teeth, and it is liable to break them off. Spring them by some other means. Joint your saw carefully, and set evenly. When you file, you want to file by ear; that is, get your ear used to it, and you will get it right every time. This is my way of doing it. I have been a sawyer for 20 years, and have all kinds of saws. B. BAKER.

Elyria, O., Mar. 1, 1889.

Your letter was shown to our foreman, Mr. Warner, and he says what you say is entirely orthodox.

NOTES AND QUERIES.

We solicit for this department short items and questions of a practical nature; but *ALL* QUESTIONS, if accompanied by other matter, must be put upon a SEPARATE slip of paper with name and address.

FLOATING APIARIES ON THE NILE.

YOUR remark at the bottom of "Floating Apiaries in Egypt" quite amused me, about your idea of the man in the stern smoking his pipe. You should see the Arabs assemble together and lie down flat on their bellies, smoking or gaming, the laziest set of people; but the hives on the boat are European shaped, while I don't think they have any of the kind, but as described in the article, and then there were certainly much more than eight.

PH. J. BALDENSPERGER.

Jaffa, Syria, March 22, 1889.

TO FOLD DRY ONE-PIECE SECTIONS.

I see considerable advice on how to fold sections without breaking when dry. There is no use to carry them into the cellar over night to dampen. Edge them up on a board and pour hot water through the grooves; let them lie for 15 minutes. Your readers will succeed every time, without breaking them. M. B. BERGEY.

Souderton, Pa., Mar. 28, 1889.

EXTRACTING IN CALIFORNIA.

One hundred miles from here, in California, they are extracting, but I do not think they get quite such fine white honey there, nor of the same flavor. Our harvest will not commence until June, although the bees are quite busy now on the blossoms, and lots of brood in the hives. I don't know how I shall like the supers, but will let you know which I prefer, in the fall. E. A. MOORE.

Reno, Nev., Apr. 3, 1889.

Bees are booming fully 20 per cent better than last year at this time. S. L. KLUTTS.
Clear Creek, N. C., April 12, 1889.

ENCOURAGING FOR CALIFORNIA.

There was 7 inches of rain three weeks since. This makes every thing boom. R. WILKIN.
Ventura, Cal., Apr. 1, 1889.

THAT ABSCONDING SWARM OF MRS. CHADDOCK'S.

The queen that was left under the goblet belonged to one of the swarms that absconded. The swarm was not joined by any other swarm, but went off alone. Generally bees do come back to the queen. I clip all my queens' wings, but I do it early in the season, and they might possibly have a new queen by swarming time. The one mentioned had her wing clipped. MAHALA B. CHADDOCK.

Vermont, Ill.

[I am quite sure, my friend, that your absconding swarm did have a new queen. Where they got her is another question.]

SIDE VS. TOP STORING.

I have 8 swarms of bees; 2 of them are in hives, with sections at the sides of the hive. Do you not think the bees would enter the sections quicker if they were on top of the hive? W. C. MARSH.

McLane, Pa., Mar. 27, 1889.

[The bees will enter the sections quicker at the sides, usually, than above; but the objection to side storage is its inconvenience, and also the fact that there is not room sufficient for storage of a very large amount of comb honey. Top storage is now generally preferred.]

BLACKS AND ITALIANS.

Why is it that Italian bees do not carry any pollen? I have two colonies of blacks and one of Italians. The blacks are busy carrying pollen and honey, while the Italians are bringing in honey only, from maple bloom. R. I. CROMLEY.

Muncy, Pa., March 22, 1889.

[The Italians do carry pollen, and, as a general thing, more than the blacks. If, however, honey were to be had, I rather think the Italians would put in their time on the honey while it lasted, and depend on getting pollen when they could not get any thing any better. Was it not so in your case?]

CHAFF FROM TIMOTHY SEED.

In March 15th GLEANINGS a friend asks about packing bees with oat hulls. I packed mine with chaff blown from timothy seed while cleaning ours. I think, so far as I have experimented, that it goes far ahead of oat or wheat chaff. Has it been tried before, and with what success? V. E. FREEMAN.

La Grange, O., March 23, 1889.

[I do not know why chaff from timothy seed would not be exactly as good as that from oats or wheat. I suppose any thing of that sort which one happens to have handy would answer about as well. I should think, however, that timothy chaff might be a little more liable to pack down tight and get moldy.]

ON THE EDGE OF 80 ACRES OF CLOVER.

I have a good place for bees at the foot of the Rockies, with plenty of clover, alfalfa, and wild flowers all around me for miles. I intend to keep my bees at the edge of a clover-field of 80 acres, and in this section it blooms till snow flies, and the flowers are in bloom from April till November.

MRS. M. A. DEPP.

Pueblo, Colorado, Mar. 25, 1889.

[I should think your place would be wonderful for bees. We should be very glad indeed to have you tell us what the crop is from an apiary on the edge of 80 acres of clover. I presume, of course, in your locality you are obliged to irrigate, to keep the clover from dying during the summer drouth.]

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

All queries sent in for this department should be briefly stated, and free from any possible ambiguity. The question or questions should be written upon a separate slip of paper, and marked, "For Our Question-Box."

QUESTION 121.—When a prime swarm clusters, it hangs in the cluster for a certain length of time; and if not hived it goes off. a. What is the longest time you ever knew a prime swarm to remain thus clustered before going off? b. The shortest?

a. For 21 hours; b. 21 hours. O. O. POPPLETON.

a. Half a day; b. ten minutes.

MRS. L. HARRISON.

a. Thirty-six hours; b. perhaps an hour.

JAMES A. GREEN.

a. I have known them to remain over night. b. I knew one not to alight at all. A. J. COOK.

Bees never do any thing invariably. I consider it wholly a matter of circumstance.

H. R. BOARDMAN.

I have had them remain 2 days. I have seen them off in 10 or 15 minutes after clustering.

PAUL L. VIALON.

I have had little experience with natural swarms. We have always had our queens clipped, and have made our increase by division. P. H. ELWOOD.

I do not remember more than two prime swarms leaving me; one of them was an hour and a half, the other I did not know when it came out.

R. WILKIN.

a. Over night. b. We have, as a rule, to hive the swarms as soon as possible, and advise bee-keepers not to defer the hiving, for no two swarms act the same. DADANT & SON.

I never had a swarm cluster and then leave. In fact, I never knew but one swarm to leave that had clustered, and I don't know how long that had been clustered. A. B. MASON.

a. For almost 2 days; b. an hour or two. I have seen a first swarm settle for about 10 minutes, and then leave for a hollow tree, in a bee-line. It had, however, a virgin queen, to the best of my judgment. CHAS. F. MUTH.

When they have alighted in a sheltered place at the trunk of a tree, or upon a fence where a limb or board protects them, I have known them to commence building comb and remain until removed. I have also seen them start to go away before I had clustered. L. C. ROOT.

a. I've known them to remain over night several times, and I think some of them remained about 24 hours, and they might have remained longer if they had not been hived. b. I think about three hours, but I am not sure, and I never knew many swarms to go off. C. C. MILLER.

I have known a swarm to thus remain two days. I always consider it somewhat risky to leave them over ten or fifteen minutes. I can not answer the second part of your question, for I never had a colony leave their new home when I knew how long it had been clustered, out of the many thousands I have hived. JAMES HEDDON.

Oh! I don't know. Small second swarms I have known to hang to the limb of a tree in the grove for several days, and even build comb; but large swarms will usually decamp if not hived within a

few hours. For many years I have not had an opportunity to observe the time, nor have I taken special pains to experiment in this direction.

GEO. GRIMM.

a. From 2 P. M. to 10 A. M., when the weather was pleasant. If a storm comes on during the night they hang till they starve, or a pleasant day comes. b. I have known of their going off without clustering at all. When they do cluster it is a rare thing that they stay less than half an hour.

G. M. DOOLITTLE.

I knew a swarm to settle on a gooseberry bush and stay there until they had built combs and hatched bees. They were then hived and worked well in the hive. The queen's wing was not cut. I have known a swarm to cluster and stay 24 hours, and then go off. I have known swarms to go to the woods, right from the hive, without clustering at all.

E. FRANCE.

What queer creatures we are! Notwithstanding long experience with hundreds of swarms, I don't know that I can answer either question precisely. Bees which come out without being seen, I often discover when they start to go off. This is often the next morning, about the time it gets to be nice and warm and dry. From the nature of the case, the exact number of hours can not often be told. And how am I to know but that in some cases they may have hung waiting for two nights? I think three or four days has been reported. Sometimes they stay always, and build comb, and continue camping out until the winter kills them off; but I have never had such a case. As to b, I dimly remember a big swarm that alighted in the pear-tree after I was tired and disgusted with swarms. I continued reading for a little while before going to attend to them; and when I went, lo, they were gone! If you will take the number of minutes a body reads when he just reads a little while, and subtract the number of minutes they had been gone when I looked—why, that will save me the trouble. If we take prime swarms inside of half an hour after they become quiet we shall not lose many, I think.

E. E. HASTY.

One or two speak of swarms remaining where they cluster, not only for several hours, but for days, weeks, and months. In California it is very common for them to build comb right where the swarm alights, and stay there permanently; but I believe that Prof. Cook and E. France are the only ones who say they have known a swarm not to alight at all. Where they have selected a location before swarming, I think quite a good many go straight from the hive to the hollow tree. The reason why so little is said about cases of this kind is because nobody sees them at all.

QUESTION 122.—*When do you prefer to hive a swarm—as soon as possible after it issues, and before all have clustered, or after all have fully settled, or some time after settling?*

As soon as they have settled. E. FRANCE.

As soon as possible after it issues.

GEO. GRIMM.

Just as soon as the majority are clustered.

P. L. VIALLO.

As soon as they have fully settled.

MRS. L. HARRISON.

Just as soon as possible after they issue.

H. R. BOARDMAN.

I prefer to hive a swarm immediately after they have fully settled. C. F. MUTH.

The hiving succeeds both ways; but it is a little easier after all the bees have settled.

DADANT & SON.

If not expecting other swarms, I prefer to allow nearly all to cluster, but I do not consider this at all material.

O. O. POPPLETON.

As soon as convenient, after all or nearly all have clustered. Generally, though, I make them return and hive themselves.

JAMES A. GREEN.

I have had so little experience that I don't know; but I suspect it may be best to hive them just as soon as they are fully settled.

C. C. MILLER.

I should prefer to hive a swarm as soon as possible after it issues. The most of my swarms cluster in a hive on the old stand. I keep one wing of all fertile queens clipped.

A. B. MASON.

If I had a natural swarm I would secure them in the hive as soon as I could after they had settled; but I am not an advocate of natural swarming. If I had a box hive I would practice a better method.

L. C. ROOT.

I prefer to catch the queen, whose wing is always clipped, and let the bees hive themselves. They usually come back in less than one hour, often in ten or fifteen minutes. They rarely fail, however, to cluster.

A. J. COOK.

I prefer to hive a swarm after nearly all the bees have clustered, under ordinary circumstances. The kind of bees and the alighting-place have something to do with it; also your method of hiving; just the right amount of fine sprinkling helps wonderfully.

JAMES HEDDON.

I aim to hive bees as soon as they have clustered enough so that my working will not prevent their settling; or, rather, I place my swarming-box among the bees and let them enter so as to be carried, as soon as settled, to the hive, thus lessening the danger of other swarms joining them.

R. WILKIN.

When I get ready. As all of my queens have their wings clipped, I can hold them in the cluster as long as I please. I have many times had them get tired of my motions, uncluster, and go off, leaving the queen hanging in a large wire-cloth cage to a limb or swarming-pole; but they soon came back and clustered with the queen again. If I did not clip my queens I should hive the swarm as soon as two-thirds of the bees had clustered, if I could get to it as soon as this.

G. M. DOOLITTLE.

Don't try to make beds before people get up, nor to hive bees before they have had their flurry out. It would probably be a little better to keep them waiting awhile; but the difference is so trifling, and the danger of losing them so serious, that no time should be lost after all are quiet. In my own practice I often make them wait until nearly sundown before they are hived, when so many swarms come out that I have not time to attend to them. This I can readily do, as I always keep a plenty of little pits in the ground handy by, into which I can chuck them; and the baskets in which I take swarms all have legs tacked on to them. When things work just right, most of the swarm alights on the basket in the first instance, and never on the limb at all.

E. E. HASTY.

Quite unanimous. Friend Hasty, however, says, "Don't be in a hurry." I have

seen so many swarms go off, however, because we had not got quite ready to take them down, that I would get a comb of brood among them just as soon as it could be done; and this brings us to 123.

QUESTION 123.—*What special means, if any, do you use to prevent the absconding of a swarm after it is hived?*

Give it a frame of unsealed brood.

C. C. MILLER.

Give a frame of brood and shade.

A. B. MASON.

I usually give the swarm a comb of unsealed brood.

R. WILKIN.

I use no other means than to give them a clean cool hive.

C. F. MUTH.

Only make them comfortable by giving shade if the weather is hot.

H. R. BOARDMAN.

I keep my queens' wings clipped; and if one should become dissatisfied I give it a comb of young brood.

GEO. GRIMM.

I put in brood, in all stages. Notwithstanding the assertion of some of our best bee-keepers, I am fully persuaded that it does good.

A. J. COOK.

By putting a frame of uncapped brood, it is very rare that a swarm will leave the hive. I use a frame of brood and one of honey.

P. L. VIALLO.

Usually none, except to place the hive in the shade if the weather is warm. On some special occasions, with peculiar or cranky swarms, I have given a frame of brood.

MRS. L. HARRISON.

Of late I have used none, but think I shall return to the old plan of giving a frame of unsealed brood, as last summer I had to hive some swarms several times a day for nearly a week. Of course, I keep my queens' wings clipped.

JAMES A. GREEN.

Clip the queen's wing; then if they try to go off, the queen can not go, and the bees will return to her. Then if I were there, or had an assistant there at the time, I would cage the queen for a week, and leave her in the hive, of course near the tops of the frames.

E. FRANCE.

1. Avoid having any natural swarms to hive. 2. Hive them in a clean cool hive, and be sure to give it proper shade. A comb of brood placed in the hive will also induce them to stay. If the wing of the queen be clipped, the bees will not go to the woods without her.

L. C. ROOT.

First swarms do not abscond except when something is offensive to bees in the hive, or when the bee-keeper before hiving has given them comb, containing or smelling of honey, which has attracted robbers. Second swarms sometimes leave the hive, to follow the young queen in her mating-trip. If you desire to be secure, give them a comb of young brood, after (not before) hiving.

DADANT & SON.

As I have never had more than two or three swarms, during all my twenty years of bee-keeping, leave their home after being hived, I find it unprofitable to take any precautions against it. When they do start out, do not expect them to alight, but get after them with double force, with the Whittman fountain pump, and, nine chances out of ten, they are yours. After re-hiving you might slip in a comb of young hatching brood.

JAMES HEDDON.

Ordinarily I give the new swarm a frame of brood, but not always. I am, however, very particular in having the hive well shaded, for two or three days at least. As I have never had a swarm abscond after being hived, my knowledge of what is necessary to prevent their doing so is theoretical only.

O. O. POPPLETON.

I do not find any special measures needful, if the bees are entirely unmixed with others. I have no especial spite against a frame of brood; but as a minute in "pudding time" may be incalculably precious, I do not usually take pains to give brood. Mixed bees are, with me, very apt to kill all the queens; and, of course, they must have brood given them in every case. To be entirely sure of badly mixed messes it is necessary to imprison them, hive and all, in a pit for several days after hiving.

E. E. HASTY.

Swarms having clipped wings do not abscond; and as I keep my queens' wings clipped, none go away; or, in other words, I have not lost a swarm by their going away during the last 18 years, having allowed natural swarming all of the time. I do not allow second, or after-swarms. If I did, the case might be different, for such queens must have their wings till they get to laying. Some put a strip of perforated metal before the entrance of all prime swarms, after they are hived, which is a sure preventive, as the queen can not go with the absconding bees.

G. M. DOOLITTLE.

I am glad to see so many friends support me in my oft-repeated instructions to put some unsealed brood with every cluster of bees, under all possible circumstances, whenever they are removed from one place and put in another. We are not always sure they have a queen, and, of course, they will scatter around and get lost very soon in the absence of a queen. The unsealed brood fixes every thing sure in any event, and indicates in a very few hours the want of a queen when such is the case. How often we hear novices worrying about their bees, and saying, "I am afraid they have no queen." Sometimes I reply, "Why, you might as well say you are afraid you have no horse, and keep looking at the outside of the barn, without even opening the stable door." I often reply, further, "Why, look and see." Then the answer comes, "Well, I can't find any queen; and, in fact, I should not know her if I did find her." I should not wonder if there were hundreds of the readers of GLEANINGS who are in just that predicament now. Well, my friend, you can tell, even if you do not know a queen. If you put in that frame of unsealed brood we have been talking about, you can tell in a very few hours whether there is a queen in the hive, even if you know almost nothing at all about bees. Just learn to watch for queen-cells, and then this comb of unsealed brood is like the steam-gauge to the engineer. He glances at the gauge, and he knows when every thing is all right. I want some unsealed brood with every colony of bees in the apiary, queen or no queen, new swarm or old swarm, nucleus or full colony. So far as my experience goes, it never does any harm, and it is pretty sure to do some good under all circumstances.

RECENT DEVELOPMENTS

CONDUCTED BY ERNEST R. ROOT.

DOVETAILED HIVES IN THE FLAT

THE feature of dovetailing on the new hives enables us to send them out in the flat for less money than we should otherwise be able to do. The expense of crating is almost nothing compared with crating ordinary hives. To crate 20 sides or 20 ends (enough for 10 bodies), all we use is four strips of wood $\frac{3}{4}$ inch square, and in length equal to the height of the pile of sides or ends, as the case may be. The dovetailing is just $\frac{3}{4}$ inch wide. Into the outside groove, at each of the four corners, we drive one of these strips. A single nail driven through the end of each one of these strips into the top board and bottom board secures the strip. Four of these strips hold the pile of sides or ends perfectly rigid without other crating. The accompanying engraving will make the idea plain.

TWENTY DOVETAILED SIDES CRATED TOGETHER.

The two light strips of wood in the perpendicular groove in each corner show how the cleats are secured. Whatever little additional expense there may be attached to dovetailing, it is entirely made up by the cheapness of the crating of the sides and ends. Even the super sides or super ends can be slid in among the hive sides or ends, and make one complete and whole package. Our foreman says that we have now made something like 1200 hives; of this number sent out, not one report has been received of this sort of package breaking. Just think of it! Four strips of wood and eight nails make the entire crating for 20 sides.

The small amount of crating not only reduces the expense of putting up these hives for shipment (a saving to the purchaser), but it reduces the weight, and, of course, the freight charges. When these hives are to be sent by express, the reduction in charges will be considerable. Can any one now say that the dovetailing is a useless expense?

HOW TO NAIL TOGETHER THE ONE-STORY CHAFF HIVE.

A good share of our customers who buy the chaff hive have trouble in getting it together right; and for their benefit I append these directions. First put together the outside shell. Nail the four pieces of siding to one pair of corner posts, beginning at the top, and making each one to reach clear up into the corner. After having nailed together the other side in like manner, then nail in the siding for the ends, the latter abutting

against the four sides as shown in the engraving. Be sure to observe this point, or the dimensions of the outside shell will be wrong. The inside box, or brood-chamber

ONE-STORY CHAFF HIVE, AND HOW TO PUT IT TOGETHER.

proper, is then to be nailed together. As the side pieces are rabbeted, no mistake can be made by getting them together wrongly. One of the bottom-boards to the inside box projects far enough to make a doorstep, as it were. On each side of this lay one of the $\frac{3}{4}$ in. square short strips. Upon these lay one of the 2x9 boards, and a similar board is to be placed on the under side of the doorstep to strengthen it. Then nail the whole together and you have an entrance or passageway much like that shown in the engraving above. See B in diagram below.

Now, instead of setting this shell down inside of the other, first nail on top of each side of the inside box the two side rim pieces, shown in the cut above. Set the inner box down into the outer shell and adjust to position. Having made the inside entrance match with the outside, nail the two side rims to the four corner posts, after which insert the two end rims, and nail to the inside and the outer shells. After having done this, slide four little pieces of tin, beveled slightly, into a groove which you will find in the miter between the end and side rims. Having made sure that the entrance match-

CROSS-SECTION OF CHAFF HIVE.

es with the side board shown in front, nail fast. The little three-cornered piece lying in front is to be nailed just below the slot-

ted entrance. The hive is now complete except packing with chaff. To do this, invert the hive, pack with chaff, preferably the wheat chaff. Tamp it well down until full. Lay in a couple of cross-strips as per diagram J J, and nail to the two opposite bottom side pieces. Level up with chaff, cover with the tarred paper, and last of all put in the bottom-boards and nail to the strips J J.

OUR OWN APIARY.

CONDUCTED BY ERNEST R. ROOT.

HOW THE BEES WINTERED.

OUT of a little less than 200 colonies, we lost two—making a percentage of only one per cent. These two colonies had plenty of stores in the hive, though none on the combs on which they were clustered. A good deal of brood was started in one side of the hive. A cold snap of weather coming on, and the bees refusing to leave the brood, starved, leaving a couple of combs filled with capped stores on the opposite side of the brood-nest. This sometimes happens with us, but not often.

DISPENSING WITH LOOSE CHAFF IN WINTERING, AND ITS RESULTS.

This year we left off all loose chaff in packing our colonies, and used nothing but an ample burlap chaff cushion. In years gone by we have used two or three inches of chaff between the cushion and the burlap sheet; but every time it became necessary to examine the colonies so packed we were obliged to gather together the corners of the burlap, lift it out with its load of loose chaff very carefully, and deposit it on the ground where it would be subject to every little eddy of wind. Using as much care as we could, we continually spilled considerable chaff among the bees, and of course this meant, the next spring, scooping out and perhaps turning the hive bottom upward, to clean it. Aside from the inconvenience in making examinations, it is considerable trouble to put it on in the fall and remove it in the spring. I accordingly decided last fall, that we would use large baggy cushions instead of loose chaff and small cushions, and the result has been just as good as any year we have wintered bees. We formerly thought it was necessary to use the loose chaff to prevent the bees from coming up; but if the cushion is tucked carefully in the corners there will be no trouble. Perhaps I should add, in this connection, that the cushion should be filled very loosely with chaff, and should be a little larger than the upper story of the hive, so as to fit snug and prevent all possibility of currents circulating down to and from the brood-nest. In another column it will be seen that our friend A. E. Manum has likewise abandoned the loose chaff, and he speaks of the very great convenience he finds in dispensing with it. It is just fun to make examinations compared to what it has been during early spring.

NEW HONEY.

Some discussion has arisen as to whether bees gather honey from maples. I feel pretty sure that our bees gathered largely from this source this year, because there was little if any thing else in bloom. When going over the colonies we noticed a great many combs containing some unsealed raw nectar. Into several of the combs I punched my finger, and transferred the same to my mouth. The flavor was not unlike that of new maple syrup. You may say that I stretched my imagination a little bit. I do not think I did, because the flavor was very distinct. The stronger colonies must have obtained an average of two or three pounds; and, as may be imagined, it had a stimulating effect on brood-rearing.

TOBACCO COLUMN.

CONDITIONS UNDER WHICH WE GIVE SMOKERS TO PERSONS WHO STOP USING TOBACCO.

First, the candidate must be one of those who have given up tobacco in consequence of what he has seen and read in this department. Second, he promises to pay for the smoker should he ever resume the use of tobacco in any form, after receiving the smoker. Third, he must be a subscriber to GLEANINGS. Any subscriber may, however, have smokers sent to neighbors or personal acquaintances whom he has labored with on the matter of tobacco-using, provided he give us his pledge that, if the one who receives the smoker ever uses tobacco again, he (the subscriber) will pay for the smoker. The one who receives the smoker in this case need not be a subscriber to GLEANINGS, though we greatly prefer that he be one, because we think he would be strengthened by reading the testimonials from time to time in regard to this matter. The full name and address of every one who makes the promise must be furnished for publication.

RUM AND TOBACCO, AND THEIR BIG FAMILY OF CHILDREN.

BRO. ROOT:—I send you a short article on tobacco. I do feel that, as Christians and refined and enlightened people, we should come out boldly on this awful evil. I tell you, it's one of the greatest causes of greater sins and poverty. People here are too poor to hardly get their salt, and yet pay \$5 to \$30 per year for this worse than useless weed, besides the awful example. I have reasons to denounce it, for it has about ruined one precious boy of mine. I speak plainly. Rum is the Devil, and Tobacco his wife, and they have a big family of children, both old and young.

Since reading Mrs. Ratcliffe's valuable article on the evils of tobacco, I have felt like shouting. Thank God, she dares speak out for the good of the world. I have proposed a tobacco pledge in the temperance pledge, but I have met such opposition by tobacco-users that it is of but little use. I am convinced that the appetite for rum is stronger by using tobacco (though I never used either), but—eyes can see. We have a new law here, forbidding its sale to boys under 16, but the desire to sell and the desire to use are so strong it will go about the same. The use of it is on the gain, and will be till the whole people take hold to put it down. But very few dare speak against it, and yet many users are honest enough to denounce it; but, by their fruits they are known.

Isn't it one reason of the cause of Christ being so slow, our church people indulging in this soul and body depressing, useless weed? I won't judge any one, but it seems to me this is a great appearance of evil; and is it not leading our precious

young boys—yes, and girls, astray? You know the best are always chosen as examples when one means to excuse a sin or bad habit. Such and such persons are sited; thus such are far more responsible than those who do not profess better things. It's a sad sight to see 7-year-old boys, with a sickening cigar, walking the streets. Who can come up and say it's all good? and who is going to chide these for so doing? Not the ones who sell it—no, for they tell us there is a big profit on tobacco, and that they couldn't do business if they didn't sell it. Doesn't the rum-seller say the very same thing? Are we as human beings willing to succumb to such ruinous courses? How easily the sale of this poison has crept into all or nearly all the grocery stores, and Christian traders too. Well, many come up and assert, that, if they don't sell it others will. I may say if I didn't rob some one, some other person would. Oh! I ask again, isn't it late enough already for even a few to fight this evil, and be a crank or a fool for Christ's sake?

Hallowell, Me.

E. P. CHURCHILL.

What you say is *excellent*, but I think all of us will have to be a little briefer, as we say in the prayer meetings, to make more room for the new converts. Just listen to them now, and see if you do not agree with me that their testimony is more inspiring than whole sermons from our most learned divines.

I need a new smoker, and I have decided to quit the use of tobacco entirely. If you will send me a smoker, if I ever use tobacco again I will pay you for the smoker.

CHAS. CRANING.

Courter, Ind.

Please find two more claims for the bee-smoker. Mrs. Fannie Bitticks says she has been using tobacco for 20 years. I gave her a few copies of your journal, and she read the same; and when she came to the Tobacco Column she said she would quit too for a smoker, and she quit. If you will send her the smoker I will see that she keeps her pledge; and if she does use it again I will send you 75 cts. for the smoker. Also please send a smoker to Mrs. Bill Ealey, Hickory Creek, Ark. She, seeing your offer, has quit the use of tobacco for a smoker. I will see that she keeps her promise.

Ozan, Ark.

J. W. TAYLOR.

May the Lord bless you, friend T., for your labors, especially as you have made such a start among the women-folks. If "the hand that rocks the cradle is the hand that moves the world," just think what the result of your labors may be, in view of future generations. We notice still another convert of yours in Anthony Clark, a little further on.

PAYS FOR THE SMOKER, BUT HAS QUIT THE USE OF TOBACCO AGAIN.

Please find inclosed 38 cts. for Terry's A B C of Potato Culture, and 70 cts. for the smoker I got on the tobacco pledge. I broke it, but I have quit again, and I hope I shall succeed this time, but I shall pay for the broken pledge.

Lynnhaven, Va.

G. W. READER.

Well, well, friend R., so you paid up for the broken pledge, and started out on a new one. May the Lord bless and sustain you, not only in giving up tobacco, but in being honest, and true to your word. If anybody

should ask me which is the worse of the two evils, to tell lies or chew tobacco, I should say that telling lies is, by all odds.

WHAT A TOBACCO-DEALER THINKS OF THE USE OF THE WEED.

Though I am still in the cigar business, and have been for many years, I think you are right in discouraging the use of tobacco in any form, with all your might. If tobacco and whisky could be entirely eradicated, the world would be benefited almost incalculably.

S. F. HERMAN.

Tuscaloosa, Ala., Jan. 16, 1889.

Why, may the good Father help you, friend H., to go a little further and practice what you preach. I do not really see how you can hand over cigars, with a clear conscience, after giving such testimony as you have above. I am sure you can not do it very long. My impression is, that the cigar business will be given up before these words reach your eyes. Please drop us a postal card and tell me if I have not guessed right.

I read GLEANINGS at Bro. Taylor's; and with the influence of your offer, and that of Bro. Taylor's, I quit chewing tobacco. Now send Bro. J. W. Taylor the smoker, and if I ever use it again I will pay you for two smokers, and Bro. Taylor will go my security.

ANTHONY CLARK.

Ozan, Ark., Feb. 14, 1889.

Three cheers for Bro. Taylor, friend C.! I believe in that kind of signing for your neighbors, every time, for it is a signing for Christ's sake.

ONE WHO HAS USED TOBACCO 27 YEARS.

A brother-in-law of mine, A. W. Banebrake, of this place, has quit the use of tobacco after being a slave to its use for 27 years. He has not used it since the 5th day of November last. He is a beginner with bees; has 5 or 6 colonies. He says if you think he is entitled to a smoker, send him one; and if he ever uses the weed again he will pay you for it. I will also go surety for him.

F. M. SHELL.

Yeddo, Ind.

And may God bless you both, friend S., for your practical way of working together. We gladly send the smoker.

I received your letter, stating that you would have to put my name in GLEANINGS in order to send my brother a smoker. I am perfectly willing you should do so; and if he ever uses tobacco again I will pay you for the smoker.

CHAS. A. PRAY.

East Lebanon, Maine.

Why, friend P., it seems to me as if God were opening up a new work for us in this issue—going security for a brother.

HAS COMMENCED TOBACCO AGAIN, BUT PAYS FOR THE SMOKER.

Inclosed please find 75 cts. for a smoker, which I got from you nearly three years ago for my son to quit the use of tobacco. He has since commenced to use it again.

HENRY L. WEISS.

Berkeley Springs, W. Va.

That is a good testimony too, friend W. Set the example before the younger ones, of promptly paying up according to promise, for such testimonies are valuable, as well as the words from those who first take the pledge.

In reply to your letter about the smoker, I would say that my friend would not let me send his name for publication, saying he did not want it published to the world that he had stopped using tobacco. I do not know that it was entirely through GLEANINGS that he stopped, but I have lent him numbers to read, and I suppose they influenced him. I did not know that you required the name of the person making the pledge, if he was not a subscriber. As he will not let me send his name, and that is the rule, I would by no means send him a smoker. He does not deserve it, he is so cowardly.

East Sydney, N. Y.

LESTER JUDSON.

Do not be too severe on your friend. Our clerks, it seems, have been a little at fault. Your friend need not give his name at all unless he chooses (although I do think it a much better way), providing somebody like yourself will give his own name and go security for his friend. This Tobacco Column seems to be pretty much all in line of "I am my brother's keeper."

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

AIR-SLACKED LIME, APPLIED TO THE SOIL, AN AN INSECTICIDE.

ON page 235 of our issue for March 15, I mentioned the use of air-slacked lime as a preventive of club-root in cabbages, and I also made mention of its property of killing angleworms, etc. I believe it has been well known to gardeners, that lime-water, even a good deal diluted, is sure death to angleworms in pots; and I have found that, say, ten barrels to the acre will kill almost if not all of the angleworms in very rich, highly manured ground for market-gardening or for strawberries. Now, friends, I am pretty sure there is something better still, right along in this line. This spring our plant-beds were all treated to a pretty liberal application of guano and lime. They were sifted on to the ground, and raked in, while the mixture gave off a strong smell of ammonia. Well, so far this spring we have not seen a single specimen, on these beds, of the little "jumping jack," or cabbage-beetle. It is the same insect that damaged the *Rural New-Yorker* folks in their potato experiments; and we have pretty good authority for saying that the larvæ of this same insect causes the club-root in cabbages, and spoils our radishes. Who has not tried to raise radishes, and found them so scarred and disfigured, and even eaten up with minute maggots, that the crop was a failure? Well, radishes raised on our plant-beds have perfectly bright, smooth leaves, with not a scar from the jumping jack, and the roots correspond exactly. There is no such pest in our plant-bed grounds; but up in our swamp, where we sowed some radishes in the peat, the jumping jacks are just as bad as they ever were, and more than half of the radishes are eaten up outright. Now, if air-slacked lime, put on strong enough, kills the larvæ, and thereby banishes the

mature insect, why will not the lime, if used strong enough, destroy *all* the bugs and insects that harbor in the ground? Prof. Cook will have to help me out here; but I am pretty sure that the striped melon-bug, and perhaps our potato-beetles, may be greatly injured if not banished by using plenty of lime. I know they come out of the ground, because I have seen them come up under my plant-boxes. The office of the lime, in liberating ammonia from any heavily manured ground, I think will recompense all it costs. Our plan is to spread the lime with a manure-spreader, after the ground is plowed and harrowed, and then harrow it again, to mix up with the soil. We have never seen plants injured by lime, no matter how strong we put it on—that is, where it is thoroughly pulverized and raked into the soil to a considerable extent. I want Prof. Cook, and W. J. Green, of our Experiment Station, to tell me if I am not at least partly right in this matter.

SENDING OUT COMMON WEEDS AS NOVELTIES.

While I am exceedingly glad to notice the energy and zeal with which our seedsmen bring out and have tested every thing new and valuable in the vegetable world, I do feel like uttering a vehement protest against the dissemination of weeds, especially where they are of little or no value. I have just now in mind the "upland water-cress," advertised in many of our seed catalogues. As we have not a running spring suitable for water-cress, I hailed the advent of an upland cress with much joy. They were started in the greenhouse, and a long row, put out in my best ground, only to find, when they arrived at maturity, that they are exactly the same thing as a weed that is found all over this vicinity, and has been for years. It seems to be a sort of cross between horseradish and wild mustard. It tastes more like horseradish leaves than anything else. The leaf is rounder, more like mustard. The root has no flavor like the horseradish at all, and I have never found anybody who cared to eat the tops at any stage, as a substitute for water-cress. If you ask what seedsmen I am driving at, my reply is, every seedsman who advertises the upland cress. You may say that he doubtless supposed it was all right. Well, my friend, I do not think that any seedsman has any business to advertise anything he has not first *tested* on his own grounds. If he has not any grounds to test things on, then I should say he has no business being a seedsman.

QUESTIONS ON CARP-RAISING, ETC.

What is the commercial value of carp, if any? How many can be raised in a pond covering one acre, if well cared for? Will they smother in winter from ponds freezing? The same questions in regard to catfish, if you can.

Is Japanese buckwheat honey-producing?

Topeka, Kan.

H. G. LYONS.

Our new book gives you all the information we have in regard to the ponds you mention; but I might answer briefly, by

saying that you can certainly raise as many pounds of carp on an acre as you could of chickens; and they are worth in the market certainly as much for food. At present I believe they bring a little more. The carp will not require any thing like the amount of care that chickens do; and I think I am correct in saying nothing like the amount of food. They will not smother in winter from ponds freezing over. We can not answer in regard to catfish. — Japanese buckwheat produces probably just as much honey, if not more, than the common kind. You must remember that all varieties of buckwheat, as well as every thing else, for that matter, that yields honey, are liable, under certain conditions, to give none at all, even though the fields be white with bloom.

RASPBERRIES AND POULTRY, IN CONNECTION WITH BEE CULTURE.

I send you a sample of ensilage from a kegful that I packed for my poultry. I had been wanting to save something of the kind for years for the long winter season, so as to help make a variety for them. The article I saw in GLEANINGS, about ensilage, last summer, stimulated me so that I put the idea in practice. I often wanted to save cuttings from a lawn, for they looked so sweet, and are about the right size for a mouthful for a hen. I shall try saving some next year. What I send you is raspberry leaves stripped from the cuttings of my bushes in the fall. They have a very sweet-smelling flavor, and I hope there will be a little left in the sample I inclose, after the journey, so that you will know how sweet they are. I made only one kegful for an experiment. It was a honey-keg capable of holding 200 lbs. I stripped the leaves off in the garden into a bushel basket. I must have put fully 15 bushels into it. I kept a weight of about 150 lbs. on them as I packed them. This weight kept me filling up a little every day for a few days, and they were pressed so tightly that they excluded the air, which I believe is all that is necessary for their preservation. Some of the leaves were half dry with the sun, while others were quite green. I was careful, however, not to put any in while there was any rain or dew on them. They were a little musty on top, but I believe that the rest of the keg is as sweet and nice as the sample sent. I usually scald it, putting a handful or two in the water that I boil or scald the ground feed with. I do not know of any thing better that can be combined with poultry than bees and raspberries. The best raspberries I ever had were picked from bushes where poultry had been allowed to run until the fruit was nearly ripe. They keep down the suckers, and the strength seems to go all to fruit.

Manistee, Mich., Jan. 12, 1889. WALTER HARMER.

The raspberry ensilage came to hand in nice shape, and is just as you describe it. I know that it is very important that poultry have some sort of green feed in the winter time; and I do not know why your ensilage will not fill the bill exactly.

ANOTHER WAY OF PRICKING OUT CABBAGE-PLANTS, ETC.

My way of pricking out cabbage, tomato, and celery plants from the seed-boxes into others a little apart, is to tilt the one end toward me on some block, at an angle of about 45°, and commence by

placing a layer of earth $\frac{1}{2}$ inch or one-inch, as the case may be, on the lower end, making it smooth and even; then lay a row of plants any desired distance apart on this, pressing them in with the left thumb to make them stick; then another course of earth, etc. At the last, begin at one side and bring the single row across. I can spread the roots, put them any depth desired, do it quicker, and I think nicer, than with the dibber.

ANOTHER WAY OF BANISHING THE "JUMPING JACK."

To prevent jumping jack from eating the first leaves of cabbage, turnip, etc., put about a tablespoonful of spirits of turpentine to 1 lb. of seed, stirring it well so that all seeds come in contact with it. As a farmer, who used it in turnip-growing, said, after they are up, pinch them between the thumb and finger and they smell quite strong. It seems quite reasonable, too, as the seed of this forms the first pair of leaves. I have not tried it, as it was too late last year when I heard of it.

Minesing, Ont., Mar. 22, 1889.

THOS. STOKES.

The turpentine may answer, but I believe I would rather take my chances by raking into the soil a good lot of quicklime, as I have already mentioned.

THE IGNOTUM TOMATO, AGAIN.

Your articles in regard to the Ignotum tomato, I read with great interest, as I have 465 seeds of the same kind. When our State fair was at Jackson last fall I noticed a beautiful plate of fine tomatoes in the exhibit of the Agricultural College. I was informed by the manager of the exhibit that they were originated at the State Farm; and, being deeply interested in the different garden plants, and especially in tomatoes, I asked the gentleman for one so I could have about the first plants outside of the original; but I see you have the start of me, and I guess you and I are the only ones now who have any seed direct from the stock grown at the Farm. By the time this reaches you I shall have part of mine planted for extra-early plants.

A. D. D. WOOD.

Rives, Jackson Co., Mich., Dec. 31, 1888.

And so it transpires, friend W., that somebody besides myself has the Ignotum. Well, it will probably be pretty thoroughly introduced another year, for we have already given away several thousand packages to the readers of GLEANINGS.

SWEET POTATOES, LEVEL CULTURE.

While the sweet-potato topic is up, I rise to state that, on loose prairie soil, it is labor worse than wasted to ridge up the ground for planting sweet potatoes. Level culture for corn, Irish and sweet potatoes, is the successful practice here, where hot dry weather can be depended upon. The sweet potatoes do not grow so long, but are larger, every time.

M. S. BENEDICT.

Crete, Neb., April 6, 1889.

I think the above depends both on the soil and season. In our locality, especially when we have as much rain as we have had for the two past seasons, the hilling-up seems to answer better for almost every thing; that is, where the hill has a broad top. This top then catches all the rain that is needed, while the furrow lets the surplus water off before our clay soil settles down so hard that it bakes like a brick.

THE "BUSH LIMA BEAN" BUSINESS.

At the present writing I have not been able to secure even a single paper of the Kumerle bush lima bean. Very likely somebody has forestalled me. I am going to have a few, however—see if I don't—even if they do cost "awful." The yellow bush lima bean, mentioned in our last issue, page 279, as coming from Minnesota, proves to be, when cooked—that is, in a dry state—just like common bush beans—no lima taste about them. It is simply a yellow bean, a little flattened in shape. Perhaps when green, however, they will taste much different—we hope so. We are going to plant largely of Henderson's bush lima bean. This, it seems to me, is certainly an acquisition; and until we can get a big one we had better make the most of this. Very likely it is earlier because of being so small, and quite likely more productive—that is, it will yield more bushels to the acre. A 25-cent package of these beans will be mailed to every subscriber of GLEANINGS who pays up all past dues to the present time, and sends us a dollar for a year ahead. Please make arrangements during the present month, if you want them, for we expect to plant every bean left in the 1000 papers, by July 1.

WHAT IS THE BEST LAND FOR ONIONS?

What is the best kind of land for raising onions? Will salt, sown on land before sowing onion seed, be useful? If so, how much would you advise me to sow to the acre? I. JACKSON.

Eau Clair, Wis., Feb. 19, 1889.

Friend J., almost any land will raise onions, providing it is made fine enough and rich enough. On some soils, salt seems to be of some benefit; but I would by no means think of investing heavily in salt until you have tried it on small patches, enough to be sure that it does good. I think you had better invest in our book on onion-raising.

THE KEROSENE EMULSION FOR APPLE-TREE BARK-LICE.

In regard to the bark-louse, I tie bits of soap on the limbs, and the water and snow wash the soap down over the insects gradually. DR. MARTIN.

Mercersburg, Pa., Jan. 29, 1889.

Friend M., tying pieces of soap in the trees would be a comparatively easy matter; and it seems to me quite likely it might answer the purpose. I presume all you need to do is to put some soap on the limbs you find visited by the bark-lice, taking pains to have the soap higher up than the insects have yet made their way.

SQUASH-BOXES; TRANSPLANTING-TUBES, ETC.

I am a farmer and apiarist, and pride myself on having a good garden. We need in this climate an extra-early tomato and watermelon. I succeeded last year, when my neighbors failed, by using the squash-boxes which you described in your seed-catalogue. They also saved my pie-plant and asparagus from a late freeze. The way I get early tomatoes and cabbage in the last transplanting, I put them into an old tomato-can; and when ready to set out I cut the bottom out and set can and plant in the ground. This also protects the plant from cutworms.

N. P. ASPINWALL.

Harrison, Minn., Mar. 24, 1889.

OUR HOMES.

By this shall all men know that ye are my disciples, if ye have love one to another.—JOHN 13:35.

AFTER dinner it occurred to me that I had better go and have my boot mended. You may be a little surprised to think that I had been off all that forenoon, wearing a boot with that great gash. Well, to tell the truth, I was in such a hurry to get off into the fields and mountains that morning, I did not think much about my boot. It did not gape open quite so wide on Monday morning as it did on Sunday afternoon. The fact is, I rather forgot about it. When Satan suggested that it looked awful, and that I really must go and get a shoemaker, and insist on his doing so much work on Sunday as a case of necessity, it looked very bad—in fact, exceedingly bad. But when I turned squarely around and shook my fist at him (not the shoemaker, but Satan) and said with energy, "Get thee behind me, Satan," he went away and did not trouble me any more. But I did think, before I started to travel on the cars again, the boot must be mended. I found a very pleasant-faced, elderly man, surrounded by his lasts and awls, right across the corner from that little stone Congregational church. I thought at first I would sit down and talk with him while he mended the boot. Then I began to think I wanted one more drink from those effervescing springs. The shoemaker kindly loaned me his shoes, which were a great deal too large, and I started for the spring I first drank from the day before. The water was very much improved—at least it seemed so, and I liked the people and the surroundings better too. When I got back, my boot was neatly finished. When I remarked that I had been up to the Ute iron spring, the people at the shop thought it incredible.

"Why, mister," said the man of the lasts, "it's almost a mile, and you have not been gone over fifteen or twenty minutes."

I then told him of my tramp of the forenoon; but I did not tell him how awkward and inconvenient his great big shoes were on that last tramp. A bystander remarked, "Why, he is almost a match for Jim —."

"What feat did Jim — do, pray, in the way of walking?" said I.

I don't remember exactly what it was, but the landlord told me of a young man who one summer went to the top of Pike's Peak on foot in one day, and came back down in the same evening, 26 miles in all. My boot was mended very neatly, and the charge was only 15 cents.

"Why, look here, my good friend, you must be a Christian to do as nice a piece of work as that, and charge only 15 cents," said I.

"You are mistaken, stranger. I try to do my work well, and to charge just about what I should like to pay if somebody else did the same work for me. But I have not been inside of any church for more than twenty years."

He said it, I thought, a little sadly, and

yet there was that beautiful little Congregational church right across the corner. I told him, in my poor way, that one who was trying to do by his fellow-men as he would be done by, as he had expressed it, I felt sure would rejoice in being among Christian people. I told him, too, that I had felt hurt and pained when the livery-man close by told me he wanted \$2.50 for a horse and buggy for only two hours. Now, perhaps I am a little uncharitable toward livery-men, and may be toward some of the hotel-keepers. It is said, that, in the winter time, when they have but little custom, they have to charge large prices for what they do get, in order to pay the expenses of keeping up an establishment; and I believe it is true, as a rule, that livery-men and those who run conveyances to and from pleasure-resorts are seldom God-fearing people. It would seem as if it were the most proper thing in the world to find God-fearing men and women to wait on those who come to view, visit, or enjoy nature's wonders in the way of mountain scenery, rivers, lakes, caverns, and the like. In regard to this matter of having nothing to do in winter, the problem is much like the one bee-keepers are obliged to solve; and I think it would behoove the hotel-keepers and the livery-men, who minister to tourists and pleasure-seekers in summer time, to make some other arrangements for men and horses during the rest of the year, and thus make prices moderate. Our rural friends, many of them, feel as if they had been outraged when they are asked to pay a dollar for a meal of victuals while potatoes bring only 20 cents a bushel.

Now, before bidding good-by to Manitou I want to ask my good friend the Congregational minister to make a friendly call on my friend the shoemaker; and may be he can take him a bee-journal if he thinks best. I wish he would also have a little friendly talk with the boys who board at the Mountain View Hotel, and may be they will be interested in looking over what I have written. I would suggest that he get on a friendly footing with the folks in the livery-stable. May be, however, it would not be best to give them a bee-journal, for it begins to occur to me that perhaps I have been a little uncharitable toward them; but when Christian people prefer not to pay the prices charged them when traveling, it is certainly their privilege to go on foot, as did your humble servant. Yes, I am not sure but we can perhaps go on our way afoot, with more genuine earnestness and zeal, than in the finest equipage. Now, we must be careful about a want of charity again right here, for it is not every one who has been blessed with strong limbs and energy to do it, as does your friend A. I. Root. If you do enjoy walking, dear reader, and are equal to the task of walking several miles on a stretch, then go this minute, if you have never done so before, and thank God that he has blessed you in this way.

Dec. 18.—It almost makes me feel sad to think the mountains are behind us, and I am told we shall see them no more. To-day, through Nebraska we have little be-

sides mammoth cornfields, and corn-cribs to match—the latter piled full of corn, but no roofs. Huge piles of corn are also seen in the fields.

What an uncertain thing "daily bread" is, in traveling! uncertain in expense, I mean. Last evening I thought to save expense by going to the lunch counter; but a turkey-leg, cup of coffee, and a piece of pie was 45 cents; and as I felt hungry still, I afterward, at another place, got a dish of oysters and a glass of lemonade, 45 cents more, or 90 cents in all, when the regular supper would have been only 75. Economy on the wrong side. At Wymore, Nebraska, I decided to patronize a one-armed soldier, and, taking a lesson from yesterday's experience, I ordered only a dish of baked beans, and coffee. He dished out so many beans, however, that I mentally figured that I was out about 45 cents, or pretty near it, again; but to my great surprise, it was only *ten cents* for the *whole dinner*. This man has a dinner-gong that goes by clockwork, while he, with *one arm*, waits on a dozen customers. I gave him some words of encouragement. What a field is here for practical Christianity! In the large city of Denver, in their large fine depot dining-hall, they charge only 50 cents for a meal. Why can not smaller towns on the railroad do as well? Another thing pleased me: Adjoining this fine dining-room, and in a conspicuous place, was a fine bath-room, close by where trains stop and start out, so passengers, while waiting for a train, can wash thoroughly all over, for *only 25 cents*. Good for Denver!

Near Burchard, Neb., the corn-cribs are several hundred feet long, and the heaps in the field are immense. Thousands of stacks of hay are also scattered over the fields. I am very sorry to notice a good many *mowers* and *horse-rakes* also. Loads of corn, and still larger corn-cribs, are now seen. A man says they get only 20 cents a bushel at the stations, and a lady says some are burning it for fuel. It makes a very hot fire, and one man melted his stove down and burned up his house by firing up too strong with *corn*.

Near Kansas City we strike the Missouri River. It is by all odds the largest river I have seen in my travels *west*—that is, rivers with water in them. I have seen plenty of immense rivers in the great West, but they lacked water when I saw them. From Jefferson City to St. Louis, the broad Missouri River occupies and covers a vast extent of land; but it seems to be, like a meadow brook, continually washing away the bank, first on one side and then on the other. The consequence is, that sometimes miles of drifting sand are interspersed with bushes and clumps of willows, indicating where the river has been at some time, while the running water may be found to have a channel less than a quarter of a mile wide. Judging from the growth of willows and weeds, this bottom land must be wonderfully fertile. It is probably, however, so liable to overflow or wash that nothing has been done with it. If this great sluggish river could be made to take a straight line, and

keep within bounds, vast tracts of the finest land in the world, it seemed to me, might be brought under cultivation. It makes one sad to look over the great barren wastes. Very often the river divides so as to leave islands of large extent in the middle of its bed. It made me think of the great Yellow River in China, that has, by depositing its sediment, and washing one way and then the other, made such havoc with human life. It seems to me one of the greatest things that the world needs at this present time is engineers who are capable of managing our great rivers. I am sure the money could be easily brought forward if we had men with brains, to expend it in the right way.

I am now nearing home, after almost six weeks' absence. Again and again have I dreamed of being back with the loved ones. Once, especially, the rejoicings of the whole family, little and big, were so like a reality that I felt troubled, and assured them there was some mistake.

"What mistake, and how?" asked my wife.

"Why, I am sure this is a dream, for I have not finished my visit. I am *still* in California."

At this there was a shout of merriment from all. As it closed she replied:

"But, *who* is dreaming, my dear husband—*you or ourselves?*"

"Why, I think it must be you, for I *know* I am in California."

Then they all laughed louder and harder.

"We, then, are only 'phantoms of the night,' are we, while you are all right? Look here, sir!" and in a saucy way she came close up to me. "Am I 'thin air?' Am I not a flesh-and-blood reality?"

Of course, I put my arms about her while I replied:

"Yes, you are, and always have been a blessed 'reality' to me," and then while the children applauded, evidently considering it a fine tableau, commenced one of nature's "dissolving views." My home began to grow dim, and fade away; and faster than railroad cars—yes, faster than even the *lightning* can travel—I was borne over desert and mountain, setting thousands of miles at naught, until I rested again in my bed in that cozy room on the mountain-side. But, hold on! One part of that Medina home did not dissolve, for I hear the children's merriment even now.

I raised myself a little in bed. By the dim light of the moon I recognized my surroundings, and remembered going to bed the night before—yes, and even got a glimpse of the little Bible that I was reading in the last thing before I went to bed, as it lay there on the pretty little stand; and vividly the text, "But whosoever shall drink of the water that I shall give him shall never thirst," came back to my mind. I am here in California, just as I declared I was; but what in the world *can* it mean—this sound of merriment and laughter that greets my ears even now—yes, merriment because I so stoutly insisted that I was in California and not at home? Have the real and the unreal become so mixed up that I can not tell positively whether I am asleep

or awake, or has that old fancy that has haunted me in my dreams from childhood, of setting time and space at naught, come true? After I had rubbed my eyes a little more, and after I had listened a little more intently to the sounds of the voices, I discovered that it was not Ernest and Maud and Connie and Caddie and Huber, after all. It was the children I had talked with the night before, in this mountain home. As the good mamma of the household was obliged to get up before daylight, they, childrenlike, wanted to get up too, and had been having their fun while I was sound asleep and dreaming of home.

At the breakfast-table, as I related the above, one of the friends remarked:

"Well, you came out ahead. You, after all, *are* in California." And I hereby give my wife, and all the rest of them, notice, that I was right and they were *all wrong*.

Dec. 19.—How good it seems to see fenced fields again, and to see every one occupied with something! Outside of Kansas City, toward St. Louis, even the small towns seem full of thrift and enterprise. The tall chimneys are sending out clouds of smoke, and little engines, scattered in the suburbs of the towns, commence *early in the morning* to send out puffs of steam. This is what I longed to see in many of the California towns. The houses along all through Missouri are well built, substantial, and pleasing in appearance, and this is true of country as well as town.

Dear readers of GLEANINGS, my long trip is ended. Those six weeks, even though away from home and friends, were six of the happiest weeks I ever spent in my life. One thing that specially contributed to make them happy, was that it was my privilege to have you enjoy them with me. I know you have done so, because of the great numbers of kind letters that have come from you in regard to those travels. I prayed as I started out, that God might help me to make the trip profitable for "Our Homes" and "Our Neighbors." and I feel like thanking *you*, for it was through your kind support that I have been enabled to make such a trip. Several months before I started, I felt that God was calling me to that kind of work. I told my wife I knew I should enjoy it, for it was, in one sense, a duty. Do you ask, why not go again, and inform my readers in regard to other countries and other localities? Providence permitting, I expect to go again after a while; but just now I am needed here. Yes, at this season of the year there ought to be two or three A. I. Roots instead of only one. In another part of this number I have been trying to tell you why I am needed at home just now. Many kind words are written to me, to which I can not reply; yes, and quite a few complaints that my old friends have not had exactly the kind of treatment they have a *right* to expect from me are unanswered. Others who are taking my place have answered them as best they could; and yet I know very well, that, at least for some time to come, no one can understand these friends I have known and loved for years, as I understand them myself. But

be patient, friends, for John and Ernest are every day learning more and more to take my place, and to know you as I have known you. It is not altogether things that dollars and cents will make right; but when you feel as if you had been neglected and ignored, do not, I pray you, feel uncharitable. At this season of the year I have steadily refused to go anywhere, even for a single day. I have even refused to talk and visit with my intimate friends and relatives, in order that I may use all the strength I have, to do by you as I would be done by. Sometimes I long to give up business, and not try to look after things as I do at this season of the year. But this feeling is wrong, I am sure. Sometimes I am told that I won't last long at this rate. So far as I am concerned, I do not know that I care so *very much* about a long life; but if by prolonging my life I can be of service to my fellows, then I want to live. If I can contribute to your happiness by living, and if I can, by influence and example, or by working when I am tired and fatigued, be able to lead some soul to "drink of the waters" I have been telling you about, then I am glad to live and glad to work.

During those six weeks while I was away, I felt remarkably free from temptation of any sort. No one vexed me, that I know of, and I did not feel tried with humanity, as I often do here at home. I met wickedness and sin; but God helped me to meet it with more calmness and courage than I do here. It would not be right or well, however, if I should spend much of my time in a life so free from care. The thought that I had *earned* my vacation and holiday helped to make me happy; but real life must be, for the most part, in the busy throng. When Jesus prayed for his disciples, just before he was about to leave them, his prayer was, "I pray not that thou shouldst take them out of the world, but that thou shouldst keep them from the evil." And so it is with us all. Christ's followers are all needed in the world. Where humanity throngs thickest and busiest, there they are needed most. "Ye are the salt of the earth;" and therefore, dear brothers and sisters, let us be content to labor on, especially while it is not for selfish ends that we are bearing toil and care and sorrow, but for humanity's sake and for Christ's sake.

By this shall all men know that ye are my disciples, if ye have love one to another.

A VISIT TO BEE-CELLARS IN NORTHERN OHIO.

ERNEST OFF ON A RAMBLE—CONCLUDED.

MR. BOARDMAN, like a good many other prominent bee-keepers, uses a square frame, the dimensions of which, if I remember correctly, are $4\frac{1}{2}$ inches inside measure, square, this size being adapted to nine $4\frac{1}{2}$ sections.

"Then you think you prefer the square frame?" said I.

"I do, sir, on account of the compactness of the brood-nest, both for brood-rearing and for the concentration of warmth while

in winter quarters. And then, again, when two of these hives are tiered up, the upper set of frames is just right to handle in a standing posture. With your Simplicity or Langstroth frame you are obliged to stoop a little more in the manipulation of the frames."

"Yes, that is true," I replied. "But then, for comb honey don't you think you lose some advantage in not having a shallow frame—that is, shallow enough to bring the brood nearer the surplus apartment?"

"Yes, there is something in this; but I think this is more than offset by the advantages of the cubical brood-nest in winter."

I noticed that, when he turned up some of the hives, the frames being so deep, some of the bottom-bars touched together, while a wide space was left between the adjoining bottom-bars. Mr. Boardman admitted that this was true too, but he did not seem to think that it made very much trouble.

On our way homeward we talked about contraction. Mr. Boardman's method of contraction is not to reduce the number of brood-frames, but to cut out the combs. To prevent the bees from storing honey in the brood-chamber he leaves on an inch or so of comb attached to the top-bar. As the bees build this downward, the queen fills them with eggs, and, as a matter of course, the honey goes into the sections. With most bee-keepers this would be considerable of a job, I imagine; but as Mr. Boardman uses a side-opening hive, he simply removes the loose side, slices off the combs, replaces the side without removing the cover or surplus arrangement. The plan is quite similar to the one outlined by Samuel Simmins, and later by W. Z. Hutchinson. Mr. Boardman has practiced this method of contraction for several years, and he thinks it is by all odds the best method. After supper that evening we got so interested in conversation, the special topic of which I do not now recollect, that, before we were aware of it, the train which I had intended to take came in, and I half a mile away, enjoying the hospitality of my friend. Well, there was no help for it, and so I waited till morning, and then Mr. Boardman kindly drove me back to Norwalk with one of his out-apiary horses, where I joined the junior Mrs. Root, or, putting aside stiff conventionalities, Elizabeth. Be sure to put the accent strong on the last syllable, if you want to get my method of pronouncing it. I regret now that she could not have made the acquaintance of the genial Mrs. Boardman, who, by the way, is not only a bee-keeper's wife, but a bee-keeper herself.

I feel now more than ever the importance of getting out and knocking off the corners. I discover in our correspondence that a great many bee-keepers have set notions. To stay at home with some of us means to get into old ruts. One of the benefits of conventions and of personal visits, as I regard it, is the breaking-down of old prejudices. I believe I am a broader man—certainly a broader bee-keeper—since visiting friend Boardman. While I do not feel convinced that indoor wintering would be better for us, or that the square frame would

be better adapted for the majority of bee-keepers, I see *more* of their merits than ever before. I mean to try his plan of wintering this year, and shall try it alongside of the chaff hives for comparison of results.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, OHIO.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, MAY 1, 1889.

Henceforth I call you not servants; for the servant knoweth not what his lord doeth: but I have called you friends for all things that I have heard of my Father I have made known unto you.—JOHN 15: 15.

GIVING THE PLACE OF PUBLICATION.

SEVERAL of our correspondents, in sending us clippings from other papers in regard to the alleged adulteration of honey, have failed to give us the address and the date of the papers copying such extracts. We are glad to have these clippings sent in to us, but we can not do very much unless we know the address and the date of the paper.

THEIR WEIGHT IN GOLD.

I WILL give their weight in gold for an ounce of Kumerle's lima beans, such as were advertised and sold by J. B. Thorburn & Co. They must be in Thorburn's envelopes, or I must have satisfactory proof that they are exactly the same that Thorburn sold. I purchased one package before his supply was exhausted, so I think I am prepared to know the genuine when I see it.

200 TONS OF HONEY SOLD.

COMMISSION firms in California handle a great deal of honey. One of them, Messrs. Lacy, Bailhache & Co., of San Diego, Cal., write us that they shipped, during 1887 and 1888, over 200 tons of honey; but as the two years preceding were poor ones their sales are usually much larger. They are making an effort to get bee-keepers to adopt the one-pound section, as they say the demand is strongly in favor of that size.

ISRAEL'S POEM—SEE PAGE 254.

BY an error of the compositor in the misplacement of the pages, some of the lines of the poem entitled "The Starving Colony" were a little out of their regular order. To get the connection right, read the first ten lines; skip eight lines; read eight lines more, then go back and read the eight lines skipped. We say this in justice to Mr. Israel. Our more critical readers may have noticed the apparent disconnection.

THE CANADIAN BEE JOURNAL AND POULTRY WEEKLY.

VOL. V. No. 5 of the *Canadian Bee Journal* has shed its tinted cover, and added in its stead eight extra pages. Half of the journal is devoted to bees, and the other half to poultry—the latter department being edited by W. C. Peter, an extensive breeder, and authority on all matters pertaining to

fowls. Altogether we think the change is an improvement, and we trust that the added subscriptions from poultry-fanciers will more than pay for the extra expense of getting out the journal. Success to you, brother Jones, in your new venture.

DOVETAILED HIVES POPULAR.

THE new hive seems to be filling a "long-felt want," as the fellow said. Orders for tens and twenties are coming in at a rapid rate; and it is really surprising what a wonderful demand has sprung up in the short time they have been advertised. Messrs. Schlichter Bros. & Co., of Burnside, Lapeer Co., Mich., have ordered 300 No. 2 Dovetailed hives in one order. We have already used up one carload of lumber for these hives alone, and have ordered another. This hive, it should be remembered, is not a new thing, but an old one that has been in use by practical bee-keepers for a good many years. The times being ripe, it has met with a hearty reception.

SWEET-POTATO PLANTS RAISED ACCORDING TO A "MULTITUDE OF COUNSELORS."

WELL, friends, *our* bed is just splendid. It was built exactly according to directions; and as we did not have spare sash it has had no covering so far, except shutters; but as there have been several cold stormy days, rendering it necessary to keep the shutters on, the plants were getting too white to suit me; therefore we borrowed some sash from one of the greenhouses, and under the influence of more light they began to be more healthy looking. Very likely, however, shutters would have answered every purpose had the plants been started a little later; and, in fact, we now have plants big enough to set out, while it would hardly be safe to put them in the open ground for at least a couple of weeks yet; therefore I think that, in our locality, there is no very particular need of having any glass at all to raise good sweet-potato plants.

WHO IS TO HAVE A PACKAGE OF HENDERSON'S BUSH LIMA BEANS FREE?

WELL, in the first place I said that any subscriber who sent us one new name; then I said that, if it were too much trouble, send us a dollar for another year, after your subscription was out. Pretty soon the subscription clerk informed me that people were asking for lima beans, just because they sent a dollar to pay up or to renew. And then quite a few asked for the lima beans who did not pay up at all; therefore I think we shall have to put it this way: The lima beans are for those who send us the name of a new subscriber. If you can not get a new name handy, pay up all you are owing on GLEANINGS, and send us a dollar for a year ahead. If you have already paid up till next January, then send us a dollar now for GLEANINGS for 1889; or send us 25 cts. for one packet, or \$1.00 for five packets, or \$2.00 for a dozen.

CALIFORNIA HONEY.

OUR friend J. F. McIntyre sends us the following note, accompanied by the three samples of the honey he mentions:

MR. ROOT: I send you a little block containing three samples of honey. The darkest is fresh filaree honey. If I have not forgotten the flavor of soft maple, it tastes a little like it, and it takes the place of soft maple here. The clearest sample is sage honey evaporated in the big tank, and represents one grade of last season's crop. The other was evaporated by the bees.

J. F. MCINTYRE.

Fillmore, Cal., April 15, 1889.

The darkest, or filaree honey, was very fair. The flavor of the clearest sample of sage honey—that

evaporated in the big tank was very fine, with the exception that there was an after pungent taste in the throat not exactly pleasant to us. The flavor of the other sample of sage honey, that evaporated by the bees, was the finest of the three—the pungent taste mentioned in the artificially evaporated sample having been entirely eliminated. To see what others would think of it, we handed the three samples to three of our printers, not telling them which we thought best. We marked them so we could tell which were which. Two of the printers immediately decided just as we had, and another one did on further deliberation. There has been a good deal of discussion as to whether honey evaporated artificially is equal to that evaporated by the bees. If the test above made means any thing, it would seem to indicate that bees have got the art down a little finer than we have. To make the test a true one, the two samples should be put side by side.

THE COMBINED CRATE, IMPROVED.

We have just changed the combined crate, which we have sold for a good many years, so that it may be manipulated in every respect the same as the T super; i. e., it can be tiered up inside of a Simplicity body; can be used with or without tin separators, and can be emptied of its sections *en masse*. Unlike the T super, it is so constructed that the bee-space may be used either above or below the sections. Although we do not recommend it, the honey-board may be dispensed with, in which case the bee-space should be put *below* the sections. It will also take in open-side sections, which the T super will not satisfactorily. While retaining all the old features of merit, it is now made much more valuable than before. We make this statement so that all those who order the old combined crate may be advised of the change. The price of the combined crate will be the same as formerly.

A "FISH STORY" AND A BAIT FOR NOVICES.

FOR several days back, correspondents have been forwarding on to us circulars from F. Andrews, 328 West Madison St., Chicago. The circular bears the stamp of a "fish story." It advertises a new hive that will prevent swarming, that will set every idle bee to work, and that will store *twice* as much honey as any other hive made. Mr. A. further claims that it will cost nothing to keep bees, as they feed themselves; that a single colony will net from \$25.00 to \$60.00 per season. It closes up by offering to sell a book, entitled, "Secrets of Bee-keeping," for 15 cents. Bro. Newman, of the *American Bee Journal*, of course, was prompt to find out whether there was any such individual. In his last issue he says they have made four trips to the address of Mr. Andrews, but that he was "out" each time. A woman in an adjoining room said he was there only a few minutes each day, and that he expected to make a trip to California in May. Mr. Newman cracks his editorial whip over Mr. Andrews' shoulders in his following characteristic way. He says:

It is useless for us to caution any one, for our readers do not send "a nickel and a dime" for any "secrets" of bee-keeping. They know better. It is the "novices" he is after. The circulars seem to have been sent to postmasters, and by them distributed into the "boxes," to catch the unwary, and many \$3.00 and "nickels and dimes" for Mr. Andrews to go on a "trip around the world."

P. S.—Since the above was in type, we have the following from friend Newman:

FRIEND ROOT:—After some six special trips to Mr. Andrews' advertised place I have got a copy of his pamphlet, and mail it to you to-day. His hive is a Mitchell, and the extractor a Mc-

Dougall. In fact, the whole pamphlet is mainly a copy of McDougall's, published in Indianapolis twelve years ago. He told the person I sent that he had no hives on hand—and sold none this year, and said it would take 10 days to get one made. He is doing nothing. T. G. NEWMAN.

The book kindly forwarded us, as above, is a pretty fair bee-book for only 15 cents, only it does not fill the bill at all, according to the circular. The principal illustration is one used years ago by N. C. Mitchell. Mr. Andrews, however, has dug out the "N. C. Mitchell," giving the hive a botched appearance. From the back cover we learn that Mr. A. sells patent medicines, etc. The engraving of the extractor is one made for us years ago by Stillman & Co., of Cincinnati, O. The word "Novice" is got rid of by some means.

We have, at this date, 8626 subscribers.

SPECIAL NOTICES.

GOOD SHEARS AT A LOW PRICE.

If any of our readers are in want of a good pair of shears at a low price they will do well to examine our advertisement in another column. We have sold in the past 6 years about 150 dozen, and have just put in stock as many more. The last lot are much nicer than the former stock.

ADVANCE IN PRICE OF SUGAR.

Of course, at the present state of the sugar market we can not sell at the prices in our catalogue. At present writing the price is 2c higher, and liable to go still higher. It will doubtless be another cent higher before it goes any lower. This, of course, does not apply to maple sugar, but we haven't very much stock of this.

EXTRACTED HONEY FOR SALE.

Now that sugars are so high is a good time to close out old honey at good prices. We have just received a lot of 20 kegs of very choice basswood honey, which we offer at \$1.50 per keg of 50 lbs. This is about as nice basswood honey as we ever had, much of it containing some clover, and the price is 1c lower than we have offered for over a year. We have also some basswood honey in 60-lb. square cans, two in a case, that we offer for 9½c per lb.

CUTHBERT RASPBERRY PLANTS AT LOW FIGURES.

Perhaps we have no better honey-plant than the Cuthbert raspberry—at least there is no other plant on which the bees seem to be so busy; and when we consider that Cuthbert raspberries are never without a purchaser—at least they never have been in our locality—it seems to me it is a good deal more rational to put out raspberries than to waste time and money on plants for honey and nothing else. Last year we sold every quart of our Cuthberts, at a price not less than 14 cents; and a great many of them, when they first ripened, brought 10 cents a pint. Now, for immediate orders, before the young plants are torn up by the cultivator, we will fill orders at the following rates: 10 plants, 15c; 100, \$1.00; 1000, \$7.50. If wanted by mail, add 5c for 10, or 25c for 100, for postage. It will be noticed that the above prices are less than half those given in our seed catalogue.

CHANGE IN SCREW-TOP GLASS PAILS.

We call the attention of our customers to the fact that we are compelled to change the pattern of our screw-top glass honey-pails. Those shown on page 22 of our catalogue are no longer made. The manufacturers have discontinued making them, and have destroyed the molds. We have been fortunate enough, however, to find another to take its place. See cut and prices in our advertisement on another page. There are now 4 sizes, and prices are somewhat changed. While on this subject I might also state that there is every prospect for another general strike among glass-blowers, which is bound to run prices up again, the same as a few years ago. At present the prices on this class of goods are as low as we have ever known them, and are sure to go no lower. The probabilities point

toward advanced prices. It will be policy to anticipate your needs and get yourselves supplied. We are laying in a large stock, and hope to hold our prices through the season, but we may be compelled to advance. Prices in our ad. will hold till further notice.

GLEANINGS ENLARGED.

You will notice that we have added 16 *extra* pages to this number. We do this to enable us to utilize some of the valuable articles which have been waiting their turn.

KIND WORDS FROM OUR CUSTOMERS.

CAN'T PART WITH OLD FRIENDS.

Of course, continue GLEANINGS. It has been the friend of my ignorance in the management of bees too long for me to discontinue it now. It is an old and true friend. Send it on
Home, La. W. F. ROBERTS, M. D.

The goods ordered of you some time ago came to hand all right, every thing in good shape. Nothing was missing. Thanks for your promptness.

MATTHIAS SCHNEIDER, JR.
Melvor, Mich., Mar. 18, 1889.

Goods came in fine order. I have not had time to examine them thoroughly. Strawberry-plants were very fine. I have not had time to count the separators, as I have just returned from the gold-mines in Lower California.

San Diego, Cal., April 4, 1889.

W. G. BAKER.

SENDING TOMATO-PLANTS BY MAIL.

Those tomato-plants came to-day by mail, and are as nice and fresh as though they had just been taken from the bed. You told in GLEANINGS that you would send 10 for 10 cts., but I have made more out of them the way we count here. G. A. HOFFMAN.
Riverside, Wash. Co., Ia.

The lawn-mower and barometer came promptly on the 13th inst. Freight \$1.48. The mower is an excellent "institution." It does the nicest and best work, with the least labor, of any thing I ever handled.

Disco, Tenn., April 13, 1889.

S. L. GREER.

I am very much pleased with GLEANINGS, and think it a very valuable paper. I am very much interested in Mr. Root's travels to California, and think the whole of the bee literature is developing and becoming more interesting.

HORACE F. GRESSMAN.
Water Valley, Erie Co., N. Y.

OUR NEW SEWING-MACHINE.

The sewing-machine came all right; freight, 60 cts. It sews as nicely as any Singer sewing-machine in this place, and is as good as their \$40 machines, and is as nicely finished.

Pana, Ill., Feb. 4, 1889.

D. C. MCLEOD.

PLEASED CUSTOMERS.

I received my goods to-day, shipped the 8th. They are all in fine shape. I can not say too much in their praise. It is no wonder you have a big trade, if your goods are always packed with the same care that I always find mine. I never looked over so many pails before, without finding some cuts. These are all perfect. My wife says that the honey-knife and extractor are very nice. E. A. PRATT.
Myrtle, Pa., April 22, 1889.

STOP MY ADVERTISEMENT.

Friend Root:—Will you please stop my advertisement in GLEANINGS? All my stock is engaged. I have used only GLEANINGS and *Popular Gardening* in advertising this spring, and am better satisfied with the results from both than with any papers I have heretofore used. THEO. F. LONGENECKER.
Dayton, Ohio, April 18, 1889.

[Your advertisement was exceedingly well gotten up, and was very attractive. I noticed it at the time, and I think that those who write advertisements will do well to study yours a little.]

THE LAST NUMBER JUST SPLENDID.

The last number (April 1) of GLEANINGS is just splendid. I was sick when it came, and thought I would only *glance* through it; but I could not lay it down till I had read most that was in it.

MAHALA B. CHADDOCK.

Vermont, Ill., April 14, 1889.

Dear Sir:—The \$1.15 worth of seeds came by mail promptly, and through the customs without any duty; and by figuring the same up at catalogue rates from the Canadian house where I had hitherto dealt it amounted to \$1.90 so in that transaction I nearly saved the price of GLEANINGS.

Minesing, Ont., March 22, 1889. THOS. STOKES.

BROTHERLY LOVE.

I enjoy your talks in Our Homes very much. Your description of the spirit of brotherly love which you say is characteristic of Long Beach is but a good illustration of the text, "By this ye know that ye have passed from death unto life, because ye love the brethren." L. A. DUGGAN.
Cuthbert, Ga., Feb. 11, 1889.

[Friend D., what impressed me at Long Beach was, that in a family where the husband was a Baptist and the wife a Methodist, they both joined in insisting that I must see one of the "very best women in the world," who lived in their town; and this "best woman in the world" was a Congregationalist; and it really seemed as if that spirit pervaded Long Beach. The members of all the different churches seemed to exhibit just that spirit toward one another. The consequence was, that when a union meeting was held it contained pretty much all of the people in the town—men, women, and children. In fact, it was a wonder how so small a place could possibly furnish such a tabernacle full of people.]

GET ACQUAINTED.

We don't believe there's a reader of GLEANINGS that wouldn't subscribe for the BEE-KEEPERS' REVIEW, to the mutual advantage of readers and REVIEW, if only all these readers were acquainted with the REVIEW and its merits. We are willing to do all in our power to bring about an acquaintance. We shall be glad to send free, to all applicants, three numbers of the REVIEW; and we will send those that are reasonable, too. The perusal of these will give a fair idea of what the REVIEW is like. Also allow us to suggest that it is not necessary to wait until the beginning of the year to subscribe, as we have a big stack of back numbers, and can supply them even from the first issue. The discussions of last year are fully as valuable as those of the present year. Price of the REVIEW, 50 cts. a year.

The Production of Comb Honey is a neat little book of 45 pages; price 25 cts. This book and the REVIEW one year for 65 cts. For \$1.00 the REVIEW will be sent two years, and the book "thrown in." Stamps taken, either U. S. or Canadian.

W. Z. HUTCHINSON,
613 Wood St. 9d Flint, Mich.

[In responding to this advertisement mention GLEANINGS.]

Green Wire Cloth,

FOR

Window Screens and Shipping Bees,

AT

GREATLY REDUCED PRICES.

The following lot of wire cloth is a job lot of remnants, and full rolls direct from the factory, that are **FIRST QUALITY**, and the pieces are of such variety of size as to furnish any thing you want. Price 1 3/4 cts. per sq. foot, for full pieces. If we have to cut the size you want, 2 cts. per sq. ft.

When you order a piece, and somebody else has got it ahead of you, we will substitute a piece the nearest in size to the one ordered, unless you specify in your order that you do not want us to substitute. The figures on the left indicate the width.

8	10 rolls, 67 sq. ft. each; 1 each of 66, 65, 64, 63, 62, 62, 54, 40, 27, 22, and 4 sq. ft.
12	29 rolls of 100 sq. ft. each; 4 of 98, and 1 each of 102, 97, 92, 75, and 44 sq. ft.
16	4 rolls of 133 sq. ft.; and 1 each of 132, and 130 sq. ft.
18	12 rolls, 150 sq. ft.
24	13 rolls of 200 sq. ft. each.
26	79 rolls of 216 sq. ft. each, and 1 each of 215, 210, and 204 sq. ft.
28	43 rolls of 233; 3 of 224; 1 of 257 sq. ft.
30	10 rolls, 250 sq. ft.
34	6 rolls of 283 sq. ft.
38	9 rolls, 316 sq. ft.
	1 roll, 42 inches, of 350 sq. ft.; 2 of 44 in., 366 sq. ft.
	THE FOLLOWING CLOTH IS BLACK.
40	4 rolls, 333 sq. ft. each.
42	7 rolls, 350 sq. ft. each.

A. I. ROOT, Medina, O.

THE BEST WAY TO GET COMB HONEY

is to get some of C. E. Jones's Southern bees. I handle more Southern bees than any other man in the North. Sometimes I get three lots in one week. I have ordered as many as fifty colonies at one time. I have men in the South that raise bees for me only, and the bees are pure Italians, and healthy. I have tried three years, and found one colony of young bees in May, from the South, are worth two that winter here. One L. frame nucleus, \$2.50; 2 frame, \$3.00. New swarms, five frames, 3 lbs. bees, in shipping-case, just from the South, \$6.00.

9d C. E. JONES, Delaware, Ohio.

In responding to this advertisement mention GLEANINGS.

FOR SALE.

Sections in bushel boxes, No. 1, \$3.00 per M. Japanese buckwheat; a complete S. or L. hive for comb honey, 75c; shipping-crates, and all kinds of supplies cheap. Price list free.

9fdd W. D. SOPER, Jackson, Mich.

JOB LOT OF POULTRY-NETTING.

Small Pieces at same Rate as full Rolls — $\frac{3}{4}$ ct. per Square Foot.

Five or more pieces, 5 per cent off; ten or more, 10 per cent discount.

Inches wide.	Inch mesh.	No. of Wire.	
			By dividing the number of square feet in this column by the width in the first column, you can ascertain the length of each piece. These figures give the number of square feet in each piece.
60	2	19	495, 445, 335, 330, 325, 280, 230, 165.
72	2	18	195.
72	3	19	720, 672, 636, 618, 558, 438, 270, 252, 222, 168, 162, 156, 156, 48.

We know of nothing nicer or better for a trellis for creeping vines than the above netting. A. I. ROOT, MEDINA, O.

NICKEL-PLATED "LEADER" SHEARS.

Elegantly Nickel-Plated Steel Shears
At Less than Half the Usual Price.

TABLE OF PRICES.

Postage.		Name.	Prices		
			One.	10	100
5	6 1/4	inch nickel Leader Shears	\$ 20	\$1 00	\$18 50
5	7	" " " " " "	25	2 30	22 50
5	7 1/2	" " " " " "	30	2 70	26 00
5	8	" " " " " "	35	3 00	29 00
6	8 1/2	" " " " " "	40	3 40	33 00
8	9	" " " " " "	45	3 80	37 00
10	10	" " " " " "	50	4 20	41 00

The above are all what are known as straight trimmers, as shown in the cut, except the 9 and 10 inch. Part of these are straight, but most of them are bent trimmers; that is, the bottom of the shear, or bottom blade, is on a level with the bottom of handle. Such large shears are generally used for cutting on a table, and this shape is preferable. We have also a few dozen 9-inch barber shears that will be put in at the same price. These shears are made near here, and we have been in the factory, and have seen them in process of making. The blades are steel laid, and all is handsomely nickel plated. Now you will want to know how we can sell them so cheap. In welding the steel plate on to the blades there will sometimes be a little flaw that can not be all taken out in polishing. These slight blemishes do not injure the shears a particle for actual service, but still they don't like to put them among the first grade of perfect goods. They are kept by themselves, and sold at a lower price. Of course, these goods are not regular stock, and are not advertised by the makers. Therefore whoever takes the lot as they come can get them very low. Having bought so large a quantity, 150 dozen, we got them at our own price, and it is for that reason that we are able to offer the above bargains. Some of the shears are perfect in every respect, except that they lack a full nickel plate all over, and some are so near perfect that you can not see any thing at all the matter with them, and they are all just as good for service as the very best grade.

WHAT TO DO,

—AND—

How to Be Happy While Doing It.

The above book, by A. I. Root, is a compilation of papers published in GLEANINGS in 1886, '7, and '8. It is intended to solve the problem of finding occupation for those scattered over our land, out of employment. The suggestions are principally about finding employment around your own homes. The book is mainly upon market-gardening, fruit culture, poultry-raising, etc. I think the book will be well worth the price, not only to those out of employment, but to any one who loves home and rural industries. Price in paper covers, 50 cts.; cloth, 75 cts. If wanted by mail, add 8 and 10c respectively.

WANTED.—To exchange bees by the pound, for buckwheat (Japanese preferred), Poland China brood sow, or thoroughbred pigs.
9d F. A. WOOTTON, Skilesville, Ky.

Wilson's No. 1 Bone-Mill,

FOR GRINDING DRY BONES, SHELLS, GRAIN, AND ANY THING ELSE YOU WANT TO GRIND.

Who has not wanted a mill of some kind, to grind up things? The coffee-mill is all right as far as it goes; but it is slow; and if you don't look out it will break. The mill shown in the accompanying picture will not only grind all sorts of grain for the chick-

ens, but it will also break it up coarsely for table use. Cracked wheat and cracked corn are not to be despised for a change in the bill of fare, I tell you, especially when you have nice honey or maple molasses to fix with it. Well, this mill will do more too. It will grind oyster-shells so as to give the hens material for egg-shells. It will also grind bones; yes, broken crockery, broken flower-pots, or any thing else. Well, by the latter operation you kill two birds with one stone—you get it out of the door-yard, and furnish the biddies just exactly what they need for grinding up the grain in their crops. If you do not believe it is better than gravel, just give the fowls a chance to tell you which they like best. The usual price of this mill is \$5.00; but you may have the mill and GLEANINGS too a whole year, for \$5.50. If you have already paid for GLEANINGS for a year, you may have the mill for \$4.50. The sieve attachment for taking out the fine dust, when crushing shells, or to take out fine meal, when cracking corn, will be furnished for 60 cents extra.

A. I. ROOT, Medina, O.

IGNOTUM TOMATO-PLANTS.

A great lot of them, transplanted and well rooted, ready to go off by first mail. Prices, 3 for 10 cents; 10 for 25 cents, prepaid by mail. By express, \$2.00 per 100.
A. I. ROOT, Medina, O.

EGGS FOR HATCHING, from pure-bred Langshans, L. Brahmas, and Wyandottes; \$1.25 per 13; 26 for \$2.00; satisfaction guaranteed.
9d J. W. & L. J. RAY, Xenia, Ohio.

FOR SALE CHEAP.

200 HALF-STORY WIDE FRAMES, AND 300 wide frames with tin, all as good as new. Simplicity sizes, will be sold to the highest bidder.
9-10d W. L. COGGSHALL, West Groton, N. Y.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

I have 12 black queens for sale, at 25 cts each.
W. P. W. DUKE, Nettleborough, Clarke Co., Ala.

I will mail Italian hybrid queens for the next 60 days: three for \$1.00, or one for \$3 cts.
W. P. DAVIS, Hyatt, Anson Co., N. C.

FOR SALE.—20 hybrid queens at 50 cts. each, shipped in Peet cage; safe arrival guaranteed.
H. L. FISHER, Milford, Kosciusko Co., Ind.

I have a few mismatched Italian queens which I will sell for 30 cts. each; four for one dollar. Warranted good layers.
J. T. VAN PETEN, Linn, Wash. Co., Kan.

I have about 20 hybrid queens, and will take 35 cents each, or 3 for \$1.00.
E. S. VICKERY, Hartwell, Hart Co., Ga.

FRESH-MADE FOUNDATION

I am still in the wax business, and will sell at the following prices:

Heavy foundation, per lb	35c
Light, for boxes	45c

Wax taken in exchange.

10d **B. CHASE, Earlville, N. Y.**

In responding to this advertisement mention GLEANINGS.

2000 LBS. BEES

READY TO SHIP BY RETURN MAIL;

Also 1000 lbs. Comb Foundation, and all kinds of supplies.

R. E. SMITH,
Box 72. Tilbury Center, Ontario, Can.

In responding to this advertisement mention GLEANINGS.

Chas. A. Stockbridge, Fort Wayne, Ind.

Manufacturer of and Dealer in

STOCKBRIDGE'S SIMPLICITY BEE HIVE,

Sections, Frames, Smokers, Comb Foundation, &c.

Mention this Paper.

Send for Price List.

MUTH'S

HONEY-EXTRACTOR,

SQUARE GLASS HONEY-JARS.

TIN BUCKETS, BEE-HIVES.

HONEY-SECTIONS, &c., &c.

PERFECTION COLD-BLAST SMOKERS.

Apply to **CHAS. F. MUTH & SON,**
CINCINNATI, O.

P. S.—Send 10-cent stamp for "Practical Hints to Bee-Keepers" (Mention Gleanings.) 11fdh

THE HIVE AND HONEY-BEE, and DADANT'S FOUNDATION.

CARNIOLAN QUEENS

From imported mothers. Untested queens, \$1.00; tested queens, \$2.00.

J. B. KLINE'S APIARY,

7-10db

Topeka, Kansas.

WE ARE NOW READY TO SUPPLY ITALIAN QUEENS to any person who wants as good as the best in the U. S. Reared from the egg, in full colonies. Tested, \$2.00; untested, \$1.00; 6 for \$5.00. Mismatched, 50 cts. Permit by Registered Letter or Money Order on New Market, Ala.

B. B. TONEY & CO.,

Padgett, Jackson Co., Alabama.

In responding to this advertisement mention GLEANINGS.

LOOK HERE!

I will sell fine colonies of pure Italian bees, with their queens, in 10-frame Simplicity hives, 10 frames all worker comb and hive new, well painted, and guaranteed to arrive at your express office in good shape. Prices: 1 hive, \$7.00; 2 at one time, \$13.00; 4, same, \$24.00. Remember the risk of shipping lies with me. Address **JNO. A. THORNTON,**
Exp. office, Ursa, Ill. **Lima, Adams Co., Ill.**
Mention Gleanings. 6-11db

B. J. MILLER & CO.,

NAPPANEE, IND.,

BEE - HIVES AND ITALIAN QUEENS.

4½x4½ Sections, from 500 to 3000, at \$3.50 per 1000; if you want more than that, write for prices. Brood-frames, T-tin Cases, Foundation, and Metal Corners. Send for price list. 11fdh

In responding to this advertisement mention GLEANINGS.

Minorcan Queens.

Very prolific, and tolerably docile. No foul brood known. Will be sent from April to October, by mail, on receipt of \$2 greenback in certified letter.

F. C. ANDREU.

7-8-9d

Port Mahon, Minorca, Spain.

In responding to this advertisement mention GLEANINGS.

IGNOTUM TOMATO PLANTS

A great lot of them, transplanted and well rooted, ready to go off by first mail. Prices, 3 for 10 cents; 10 for 25 cents, prepaid by mail. By express, \$2.00 per 100. **A. I. ROOT, Medina, O.**

Vol. XVII.

MAY 15, 1889.

No. 10.

TERMS: \$1.00 PER ANNUM, IN ADVANCE; 2 Copies for \$1.90; 3 for \$2.75; 5 for \$4.00; 10 or more, 75 cts. each. Single number, 5 cts. Additions to clubs may be made at club rates. Above are all to be sent to ONE POSTOFFICE.

Established in 1873.

PUBLISHED SEMI-MONTHLY BY

A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS than 90 cts. each. Sent postpaid in the U. S. and Canada. To all other countries of the Universal Postal Union, 18 cts. per year extra. To all countries not of the U. P. U., 42 cts. per year extra.

OUT-APIARIES—NO. VII.

HAULING BEES; MANAGEMENT OF HORSES AMONG BEES.

I HAVE hauled a good many loads of bees—so many that I probably shall never get much more used to it than I am now; but I confess to you that I give a sigh of relief every spring when the last load is hauled, and the same thing happens in the fall. I'd like to impress this on your mind pretty strongly; for if you are not very careful you may get into such trouble that you will wish you had never had anything to do with bees. I mean trouble in getting horses stung, for you need anticipate no special trouble if you move your bees by rail. I think I would rather not have a very fractious horse to haul bees, although if no bee ever gets out in any way, there is no more danger than in hauling so many boxes of potatoes. But I never expect to become such an adept at the business that occasionally a bee will not sting my horse, and I am not sure whether a horse becomes used to bees so that, after being stung a few times, he will care less for them, or whether he becomes more nervous about hearing them fly around him after experiencing their sting. I am more inclined to the latter view; so at such times I am quite willing to endure a horse that is lazy and not easily stirred up.

I am not sure whether all horses need the same treatment when attacked by the bees; but I suspect they do, from what little I have learned about others, and the experience I have had with two of my own. A bee attacks a horse at the head oftener than anywhere else, and his first impulse is to get to some post or tree where he can rub his head. A careless observer, seeing a bee attack a horse which is hitched to a wagon, would say that the first impulse of the horse is to run; but I think he tries to

run for the sake of getting to some object where he can rub his head. So when a bee stings a horse on the head, or even annoys it by flying about it, the first thing is to run to his head, and, with one or both hands and forearms, rub his head all over, unless you know where the sting is, and then you will do better to devote your attention to that particular spot. You say that a sting only pains worse to rub it. Never mind; we're not trying to save the horse pain, but to save him from running and smashing things. Let me caution you to look out that the horse does not knock you over with his head, for in trying to rub his head he will strike against you. If you are driving on the road, and a hive springs a leak, unhitch your horse as lively as you can; get him to a safe distance, and hitch him till you get every thing secure. I once had an old hive break so badly on the road, that the only thing I could do was to unhitch and take the team some distance ahead, unload the hive, and leave it on the roadside (till next morning), then draw the wagon a short distance by hand before hitching on. You know how persistently a cross bee will sometimes follow you around. Now, don't go near a horse till you have got rid of such a bee, even if you have to make a detour a long way around.

I have learned to be cautious with a horse, even if there is not a hive in the apiary. One fall, after all the colonies had been hauled home from the Wilson apiary, we went over to bring home the last load of empty supers. My wife and her sister were loading on the supers, and I was occupied at some distance when I was surprised to hear them calling out that the horse was being stung. Charlie had hauled home the last load of bees alone, and in an empty or nearly empty super that he had taken off one of the hives, there were a pint or so of bees. The horse was hitched with his head close to the pile of supers; and when this super was slightly lifted,

one or more bees came out, and the super was immediately shut down. But the horse began to plunge, and knocked the pile of supers over, when the bees poured out upon the horse. By the time I got there he was rearing and plunging, the bees all over him. Failing to untie him I took out my knife and cut him loose, when he threw himself flat on his side, fortunately breaking nothing, and refused to stir for my kicking. I stuck my sharp-pointed knife into his side, which perhaps he took for an unusually bad sting. At any rate, he sprang to his feet and started for a lively trip around the orchard, I hanging on by the bits, ardently wishing something might stop us, but pretty soon we stopped ourselves, pretty well tired out, and while I hung on, the others unhitched him from the wagon and I let him make a few circuits of the orchard, when I caught him and led him into the barn, very tired, very wet, and probably very sore, his head hanging down as if meditating on the uncertainties of piles of empty supers. I was in my bare head, and got one of the worst stings I ever had. All this is told to try to make you careful about bees and horses.

C. C. MILLER.

Marengo, Ill.

I am real glad that you have touched upon this matter of what to do with horses when they are stung by bees. I do not know but that I am wicked enough to feel glad that you got pulled around the orchard bareheaded, devoutly wishing that something might "stop us." It never occurred to me before that a horse, when stung by a bee, wants to rub his head against something; but since you mention it, I have over and over again seen horses act in just that way. Poor fellows! They have not any hands to grab the vicious bee, and all they can do is to rub their heads against something to keep the bee off. Yesterday I got quite vexed with old Charlie because he pushed his collar against the limbs of the apple-trees when he was cultivating. I finally surmised that his neck was warm and sweaty, and very likely he wanted to scratch, and he reasoned with horse sense that the limbs of our young apple-trees would do the scratching about as cheap as anybody. Poor fellows! I often feel a great deal of sympathy for them. They are harnessed up and made to go. They can not tell when they feel bad and uncomfortable. In fact, if they should undertake to tell, in any of the ways that dumb folks talk, they would get a sharp scolding, and may be a whipping. I shall certainly try to rub a horse's head whenever I see one stung again. In fact, I have often seen Meg, when a vicious fly got on her head, stop right in the road and turn around, and by means of vigorous nods fairly beg to have somebody get out of the buggy and kill the fly. I don't think it would make the sting hurt any worse on a horse to rub it. I have often felt impatient with drivers of horses because I could not get them to move lively when bees were in dangerous proximity. Once while harrowing close to the apiary a swarm of bees acted very much as if they were going to settle somewhere on the \$400 team. I yelled out to the driver to get his team out of the way with all possible dispatch. He first stopped to ask two or three

times what I wanted. Then he began leisurely to move the lever so as to lift the Acme harrow on to the wheels. By that time I got pretty much in earnest. I yelled out to him to start up his team and make tracks if he knew what was good for him. One second more, and there would have been trouble. The bees followed the team a little way; but when he got under way, the horses took him to a place of safety pretty rapidly. I have sometimes wished we had some arrangement to let the horses entirely loose from the vehicle by pulling a single lever. If we could get the horse loose from the wagon, there is not much trouble in getting him away from the bees, usually. Ernest here informs me that our friend A. E. Manum is a harness-maker, and that he already has something touching on this very matter, forthcoming shortly. Yes, friend M., we are all going to try to be more careful when we have horses among the bees. We thank you for your timely warning.

PARTHENOGENESIS.

PROF. COOK TELLS US HOW WE KNOW IT IS TRUE.

DEAR MR. EDITOR:—I have long known of Ulivi's views in regard to parthenogenesis, as stated by your correspondent, F. C. Andrew; and as he and you request, I will gladly give my reasons for thinking him mistaken.

First, for the younger bee-keepers, let me say that parthenogenesis, or agamic reproduction, means genesis or reproduction without males. That is, a female that has never met a male can produce young. This is illustrated in coral animals, where each alternate generation produces without males, and we call it then alternation of generations. Among insects it prevails in all the summer broods of aphids, or plant-lice. This any one can easily demonstrate. We have only to take a young louse, as soon as it is born—the eggs hatch within the mother-louse—and isolate it—that is, put it on a plant all alone. It will grow, mature, and produce many young lice. This louse has never seen any other louse, male or female, except its own mother, and that only for a brief natal moment. It would have been the same had we left it on its food plant undisturbed; for at this season—midsummer—there are no males at all. The separation was simply to demonstrate that parthenogenesis is a truth. In case of bees, parthenogenesis extends only to the production of the males, or drones; that is, if an unmated queen lays an egg, or if any queen lays an unimpregnated egg, that egg hatches, and a drone is the invariable result.

Now, I am sure that this is true science, and not mere theory. First, because such noted bee-keepers as Dzierzon and Berlepsch, and such able scientists as Siebold and Leuckart, in Germany, and such Americans as Langstroth and Leidy proved it. Again, I have also proved it. I have several times clipped a queen's wing so she could not fly, as soon as she came from the cell, and in no case but one did I ever secure any thing but a drone-laying queen. In many cases these queens were in hives or nuclei with no drones, and so guarded that the drones could not enter or the queens go forth. So Ulivi's statement, that they were impregnated in the hive, could not be true. But I have stronger

proof. It is very easy to tell with the microscope whether or not a queen has met a drone. If so, the very active sperm-cells are easily found. I have dissected these drone-laying queens repeatedly, and always failed to find the spermatozoa. They were not there. So I am positively sure that the queens never mated; and yet they produced drones, hence I know that parthenogenesis is true.

Again I have dissected fertile workers—several of them—and though they laid eggs, I even found eggs in their ovaries; yet all produced drones. Moreover, they had no spermatheca. True, the little rudiment, small and functionally imperfect, was present, but no sign of an active spermatheca. Ulivi says these are real queens, and have mated. It will be difficult to convince such apiarists as Viallon, of Louisiana, who sent me several fertile workers at one time, that these are queens. They have the form and general structure of workers throughout, except that they are fertile. From dissection I know they never had met, nor was it possible for them to meet a drone. They were not sufficiently developed. Many other insects, like ants and wasps, illustrate this law as exemplified in bees; while other insects, even as high as moths, have been known to produce eggs that hatched, and yet the moth had never been near a male.

The statement of Ulivi, that this theory is announced to favor breeders of queens, is not worthy of notice, certainly in America. Many, I think most of our queen-breeders, are men of high character, who would despise to misrepresent or deceive. To say that Dzierzon and Berlepsch proposed this theory with fraudulent purpose or intent, is very unkind and uncalled for. Both were grand men who would scorn such a thought even—men who thought no evil. Such insinuations need no refutation. Our bee-keepers are too intelligent to heed them for one moment.

Agricultural College, Mich. A. J. COOK.

FIXED FRAMES.

FRIEND HEDDON CONSIDERS THEIR ADVANTAGES.

I WAS deeply interested in reading the answers to Query 117, which is as follows: "If you use all-wood frames, do you prefer to have them hung on metal rabbits or on a plain wood bearing, in the production of honey?"

I believe all who answered this question, did so honestly from their experience as honey-producers. A few years ago I should have answered it the same as the majority of them did, because I should have answered it from my standpoint of knowledge and experience at that time. Brother C. C. Miller says, "On a plain wood bearing. Then they are always ready to haul without fastening the frames." Brother Geo. Grimm says, "I use all-wood frames hung on wood bearings. Metal rabbits are a source of constant annoyance to me, and the few that I had I have discarded."

Now, friend Root, I am going to attack your foot-notes next, for you are also one of those fellows who pitch in among the answers. You say that a few have been bold enough to discard frames altogether, having a shallow brood-case something like Heddon's, and letting the combs be built in solid. Yes, sir, that was the very idea I had years ago, when I wrote an article for which you called me a box-hive bee-keeper, and made a box-

hive department, fully expecting that I would have that department to dance around in all by myself. That kind of a hive would have one splendid advantage. Having no bottom-bars in the way, how easily you could look into every thing! But you see with my new hive I have a § bottom and top bar, so I could get nearly as great an advantage in that direction. Well, by experimenting carefully with this and various other styles, I found I really did want the frames, especially where full sheets of foundation are used.

Nearly all of those who have answered this question contemplate pulling the frames out and in, very frequently. None of them contemplate a hive with which nearly every bit of the useful manipulation, such as the practical honey-producer desires, can be done without ever removing a frame. Another thing: The close-fitting frame, which they all have in their mind's eye, works upon an entirely different plan from the manner in which I use it. When father Langstroth visited me and practically handled my hive, he would not believe, before he had put it to the test, that he himself could handle eight of these close-fitting frames quicker than he or any one else could handle the suspended frame; but he found he could. He found an arrangement or adjustment of which he had not hitherto conceived. Let me give you the exact words of the grand old benefactor whose mind and conception of mechanics seems to be as bright as ever it could be. I quote from his article in the *American Bee Journal*:

1. Before I saw the easy working of his frames (EVEN IN HIVES WHICH HAD BEEN OCCUPIED FOR SEVERAL YEARS BY BEES), with close-fitting uprights (I prefer this French term to our word ends), I could not conceive how they could possibly be handled as rapidly or safely as the Langstroth frames. The propolis trouble alone seemed to forbid this. Judge of my surprise, then, to find, that, by leaving no space for bees to get between the uprights and the cases holding the frames, and by keeping the touching surfaces of the uprights so closely pressed together by the thumb-screws as to leave no joint open wide enough for bee-glue, he had actually reduced the propolizing propensity of bees to a minimum.

My knowledge of the trouble and delay in manipulating all the previous styles of close-fitting uprights, led me to think that it would be quite difficult to handle the Heddon frames. To find that I was mistaken on this point, was a greater surprise than the way in which the propolis difficulty was met. In handling Langstroth frames of the standard depth (and still more with deeper frames), bees are often hurt between the uprights and case—a thing impossible with the Heddon arrangement, while at the same time the uprights of his case—as they go down into the hive, when a frame is put back—only push the bees away instead of pinching them between their closing surfaces. When the Langstroth frames are put back, even by experts, it often happens that they must re-adjust the spacing, to get room for the last frame; whereas the Heddon frames always go to their proper places. As a matter of fact, then, the Heddon frames can be safely handled with more rapidity than any in previous use; thus securing all the advantages of close-fitting uprights without their old inconveniences.

It seems to me, friend Root, that the whole thing is summed up in this way: Bee-keepers who have educated themselves to the constant handling of combs, prefer the hives arranged as are tenelements, and they want the metal rests, and laterally movable frames; but those who have found themselves compelled to handle 200 colonies of bees in the same length of time they used to handle 100, have found they must handle the hives more, and not open them so much. This is just what I found,

and what led me to the invention and construction of a hive with which I could accomplish all that the practical, successful honey-producer needed, and that, too, almost instantly, with scarcely ever needing to remove a single frame. That accomplishment meant closed-end frames; and when Dr. Miller and George Grimm mention the advantages of "hauling" hives of bees, and the "constant annoyance" of having frames rattling round, they have no idea what a comfort it is to use a hive with shallow, straight combs, with which the usual advantage of lateral movement plays no part. The hives can be carried in and out of winter repositories, as well as being handled every way with that security, safety, and convenience with which only fixed frames can be handled, and at the same time, when desired, each frame can be handled quicker than the suspended frames can be operated.

I am this day in receipt of a letter from M. M. Baldridge, which is only a sample of many others received, telling how much better his bees wintered in extremely shallow frames than in those of the Langstroth depth, or deeper. That is just my experience. The very shallow frames are the best for wintering, likewise for early spring breeding. The reasons for these facts are obvious; but this article is getting too long, so I will close by saying that, since the invention of comb foundation, and the arrangement and adjustment of frames as described above, the suspended frame has had its day, and will soon become obsolete with the practical honey-producer who feels himself compelled to produce his crop with the least possible outlay of labor, which is the main factor connected with the cost of honey production. JAMES HEDDON.

Dowagiac, Mich., Apr. 9, 1889.

CLOSED-END FRAMES.

SOME GOOD ARGUMENTS IN THEIR FAVOR.

FRIEND ROOT:—I am glad to see you admit, in your comments on Questions 116 and 117, that there are good reasons why a honey-producer should prefer closed-end frames.

No doubt it seems a wide departure from the metal-cornered frame hanging on metal rabbets, and it probably is difficult for one who has used only such frames to believe that an all-wood frame, with the ends jammed up close together, to be propolized by the bees, can be as readily handled. I remember when we were at the Chicago convention, in 1887, you asked me what kind of hive I preferred; and when I answered that I did not exactly know, only that I was sure of two things—that I wanted a shallow hive and one with the frames at fixed distances, a curious, half-doubting smile spread over your face as if you would say that you were afraid I was making a mistake. Well, I am very much of the same opinion yet. While I am sure that I want shallow, closed-end frames, I am not yet quite certain as to the best kind of a hive to make them into. I have experimented, and am still experimenting largely. As a result I am now using several different kinds of hives and frames, which is not so inconvenient as you may suppose, as the hives are all interchangeable in their parts; and when I decide which kind I like best, the others can all be changed to that with but very little trouble.

One advantage the closed-end frame has over the

hanging frame, as regards the time required to handle them is, that you waste no time or labor in spacing them; and another is, that fewer brace-combs are built between them, as the distance between comb surfaces is seldom varied.

I have known, ever since I have kept bees in these shallow fixed-frame hives, that my bees wintered better in them than in the deeper hanging frame; but I had always laid it to other reasons, for the most part. Since reading the answer of L. C. Root to Question 116 I am convinced that the closed-end frame deserves more credit for this than I had supposed.

You know I have always argued against upward ventilation in the winter and spring. This morning I was examining some of my colonies, just brought from the cellar, and it gave me great satisfaction to be able to stand the hives on end, or turn them upside down, thus learning all I wanted to know of their condition, without removing the cover or making any crevices around the top of the hive. I believe that, in the spring, when the weather is cold and propolis scarce, the less plastering we make the bees do, the better.

Of 116 colonies put into winter quarters, 31 of them in a cellar, the rest outside, all are at present in good condition but two, one queenless and one so weak it was united.

J. A. GREEN.

Dayton, Ill., Apr. 10, 1889.

FRANCIS HUBER.

HIS LIFE AND SERVICES TO THE BEE-KEEPING WORLD.

WE take the following very interesting sketch from Gravenhorst's *Illustrated Bee Journal*. It was written by Mr. T. Kellen, of Luxemburg. The translation is furnished by W. P. Root.

Francis Huber, by his investigations and researches in apiculture, did more to promote this science than all his predecessors who had employed themselves in the study of this interesting insect. It is his discoveries alone that marked that golden age in the history of apiculture which is destined to remain for all ages. Huber's observations are not only of the greatest importance of themselves, but wonderful for the manner in which they were made; for Huber was blind.

This distinguished man was born in Geneva, July 2, 1750. He was the son of a prosperous and respectable family, which as early as the 17th century were celebrated for their knowledge of the arts and sciences. His father, John Huber (born in 1722, died 1790), was well known on account of his attachment to the celebrated French philosopher Voltaire.

From his earliest youth Huber showed a passionate predilection for natural history, and he applied himself to study with such zeal as to endanger his health, so that at the age of fifteen the reflection of blinding snow destroyed his sight. If ever a man bitterly deplored the loss of eyesight, that man was Huber. But his misfortune did not hinder him from applying himself to the study of those insects for which he had an especial liking; namely, the bees. It was this little insect that turned the darkness of the investigator into day; for Huber was the first to see clearly into that domain which to the best eyes had previously remained in darkness.

Huber did not lose his vigor of mind, for he went

forward in the study of bees; but he could do this only by the help of his wife, Marie-Aimée Lullin; his niece, Miss Jurine; and, above all, his servant Burnens. He himself manifested the most untiring perseverance and the greatest ingenuity, so that, by Burnens' sagacity, all of Huber's experiments with bees were practically demonstrated. Miss Jurine, who loved natural history above all else, supplemented Huber's work all she could, fearing not to take up the dissecting-knife and microscope in his aid. She was the first after Swammerdam to demonstrate that worker-bees are females. She it was, too, who, with Huber, established the principles on which the sages of our century grounded the doctrine of parthenogenesis. Besides that, Miss Jurine was Huber's secretary, full of willingness and self-devotion. Every day she noted down the results of the new investigations, and she also wrote the letters which Huber dictated to Charles Bonnet and his friends, and imparted to him the results of his labors, and directed their attention to numerous questions relating to bees.

FRANCIS HUBER.

Huber's interest in bees was greatly enhanced by the researches and writings of Swammerdam, Reaumur, Schirach, and probably also of the celebrated Swiss bee-keeper, Duchet de Remauffens, and the Messrs. Gelieu. As a conclusion to the investigations of these men, it was possible for him, in spite of his unfortunate surroundings, to add greatly to the realm of apiculture; hence we may not forget that he everywhere encouraged and helped others by the nobility of his life.

In his later days he lived retired, but in peace, at Lausanne, where he died Dec. 22, 1832, at the age of 83.

Huber's discoveries are known to scholars through his letters to Charles Bonnet; and they made his name so celebrated in all Europe, and even in America, that for many years he was recognized as the greatest apicultural genius; and even yet Harnet calls him the greatest of the lovers of bees (*le plus grand des apiphiles*). It was in 1796 that his first epoch-making work was brought to light, bearing the title, *Nouvelles Observations sur les Abeilles* (New Observations on Bees). His son, Peter Huber, in

1814 issued the work in two editions, and added thereto an appendix in regard to the origin of wax.

Huber's work is, not only on account of its contents, but for the peculiar circumstances under which it was first brought to light, entirely without parallel in scientific literature. The recognition which it received was universal, so that, after the first appearance of the work, Huber was received into the French Academy of Sciences, and other scientific bodies.

The New Observations were translated into nearly every European tongue. The Saxon commissariat Riem, in Dresden, translated it into German in 1798, and Pastor Kleine, of Luehthorst, translated it again in 1856, and published another edition in 1869, with notes.

Huber, by his observations on the secrets of bee-life, made clear what the most sagacious and learned observers from the time of Aristotle and Aristomachus down to Swammerdam and Reaumur had sought for in vain; and it is to be the more regretted that some German bee-keepers of great influence, such as, for instance, Spitzner and Matschka, gave him no recognition.

He gave interesting explanations in regard to the habits of bees, their respiration, the origin of wax, the construction of comb, etc. He confirmed Schirach's proposition, that, by a change in the mode of treatment and food of larval bees, queens could be reared from worker eggs, and showed, likewise, the influence which the cell exerted on the insects. He showed further, that not only the queen but a certain species of worker-bee could lay fertile eggs, and showed, likewise, the function of drones. In opposition to Braw, Hattorf, Contardi, Reaumur, and others, who held very peculiar opinions in regard to the fertilization of queens, Huber showed that the fertilization takes place outside of the hive, at the same time that drones are flying, and that the union is effected in the air, and that the queen, on her return from the flight, has adhering to her body the evidences of fertilization, and that egg-laying takes place about 46 hours afterward. These and numerous other experiments he often proved in his works with the utmost exactness; and especially did he lay down the most important and interesting information in regard to feeding bees, their method of building, the leaf-hive, foul brood, etc., in his letters to an eminent apiculturist in Switzerland, Mr. C. F. P. Dubied. These eighteen very long letters of Huber, the first of which was dated Oct. 12, 1800, and the last Aug. 12, 1814, were written partly by Huber himself, partly by his wife or daughter, to whom he dictated. So far as I know, this correspondence has never been translated into German, which is greatly to be regretted.

When one reads Huber's observations, it becomes evident that the author interested himself in bees, from a scientific standpoint only. In one of his letters to a friend, he writes that he never realized any material benefit from bees. This is easy to understand when we consider that his experiments with them lasted the entire year through, and were conducted only for the sake of science; and one naturally inquires how he found bees enough to carry out his numerous experiments.

Mr. Kellen here gives a picture of Huber's leaf-hive, which we will describe briefly in our own words, simply basing our figures on his.

Take, for instance, ten single-pane win-

dow-sash, about 13x20 inches. Stand them up the long way, one touching the other. Only the two outside frames have glass in them. Fasten the frames together with small cleats, putting a small screw through the end of each cleat. The screw penetrates the edge of only the outside frames, or those that are glassed; otherwise the inside frames could not be removed for the purposes of observation. Provide an entrance and put on a roof, and there you have the hive that Huber used. Sometimes, however, these frames were hinged at the back, and then they could be opened at one side like the leaves of a book. Mr. Kellen says:

It will be seen that this leaf-hive was the fore-runner of the Dzierzon frame. In fact, at first the frames turned outward, while the movable frames are inside. Such was the service rendered by this blind investigator, who in apicultural science, at least for his time, made true the little legend of his native city, *Post tenebras lux*—light after darkness.

In the above interesting account of Huber's work, it seems a little significant that two of his most valued helpers were women—his wife and Miss Jurine. Woman's place in the industries, inventions, and progress of the world, was beginning to be felt, even in the time of Huber; and oftentimes as I sit in the office and listen to the click of the type-writers (there are four of them now), and see how much of the brains and head-work of our establishment is in the hands of womankind, I deeply ponder. In a great many ways in these latter days, God seems to be choosing the weak ones of the world to confound the mighty.

HIVES.

CLOSED-END FRAMES, ETC.

THIS being the subject I have studied the most, my enthusiasm leads me to say a few words regarding Prof. Cook's article on pages 349 and 350. The professor asks if the advantage gained by the use of close-fitting frames doesn't cost too much. By this I apprehend he must mean to ask if we are not losing more than we gain by parting with the lateral movement of suspended frames. Now, I wish to say that all depends upon the construction of the closed frames. Mr. Langstroth said, and truly too, that the one main objection to all close-fitting frames of the past was the danger of pinching bees when they were put up together sidewise. Well, now, with my arrangement of the tight-fitting frames they are not put up together in that way, and do you not see that I can put a frame down into the hive and take it up much more rapidly, and not only that, but with no danger of pinching or mashing the bees, than we could when using the Langstroth frame? Heretofore the frames have been put together sidewise because they could not be shoved down, pushing them through all the way from top to bottom, removing the possibility of pinching a bee, because they were liable to slide sidewise; but with my arrangement there is no such thing as pinching a bee, either between the uprights on each side or between them and the case. However many bees may be there, they must be pushed out of the way. How is it when you lift a suspended

frame? You know that, unless nerve and time are expended, you are liable, by a little sidewise motion, to pinch bees—not mash them, but pinch them between the uprights of the frames and the case. You hardly notice any thing out of the way; and when you get a jab on the hand or nose by the pain-producing javelin of this bee, you hardly know why it comes. You can not imagine how much less stinging we have, and how much more amiable our bees seem to be, when handling them in the new hive, from whence we seldom move a frame, being able to accomplish all that the practical successful honey-producer could possibly ask without such removal. I mention the foregoing, because friend Cook really makes a mistake in classing my new hive with the Huber and other close-fitting frames. The shallowness of my frames, especially since the adoption of wired foundation, making good, straight, regular combs, the lateral movement of the frames is almost useless.

THE DOVETAILED HIVE.
